Germany.—German and Austrian aluminum production in 1942 has been estimated at 350,000 tons. Larger production, desperately needed to supply the Luftwaffe with planes, is thought to have been retarded by shortages of power, labor, and transportation. The power stations supplying electric energy for the aluminum plants are mostly based on lignite; labor for lignite mining and transport for bauxite seem to be the principal limiting factors in the German aluminum industry. Reports indicate that most German bauxite imports are from Hungary and southern France since transportation from these sources is easier than from the more remote bauxite districts of Croatia, Italy, and Greece. Intense effort is being put forth to recover all possible light-metal scrap, and remelters have been instructed to concentrate on 14 grades of remelted aluminum. Most of these grades are blended with virgin ingot for use, but some are sold direct to foundries by the Association of German Aluminum Smelting Works.

Gold Coast.—Deposits in the Gold Coast became one of the major sources of bauxite for the United Kingdom aluminum industry in 1942. Development is progressing rapidly, and it is hoped that 120,000 tons of ore will be produced in 1943. Plans are to increase annual production to 240,000 tons by the end of 1945. All bauxite being produced at present is from the Sefwi Bekwai area in the western province of the Colony. Britain wishes to obtain rolling stock and mining equipment from the United States to facilitate shipping and increase the capacity of the mines.

Major deposits of bauxite in the Gold Coast are the following: Yenahia group, Ashanti, where reserves, including highly ferruginous bauxite, are estimated at 168,000,000 tons, some of which analyzes 1 percent SiO_2 and 63 percent Al_2O_3 and is 20 feet thick; Affoh group, Sefwi Bekwai, with estimated usable reserves of 32,130,000 tons; Asafo, N. W. Sefwi, 5 miles north of Asempanaiye, where 15,000,000 tons average more than 55 percent Al_2O_3; and Mount Ejuanema,

Digitized by Google

Kwaho, 2 miles from the railhead at Nkawkaw and 112 rail miles from the port of Accra, with estimated reserves of 4,000,000 tons of massive and rubbly bauxite. Numerous other minor deposits are scattered throughout the country and occur mainly as cappings of aluminous laterite on flat-topped hills. High-grade chemical ore exists in the Gold Coast to some small extent, but on the average the bauxite found here is comparatively low in silica and high in iron. Tremendous tonnages of metallurgical ore are available.

Hungary.—According to recent reports the world's richest bauxite deposits have been discovered in the mountain region of Borzoeny, Hungary. No statement of the size of this deposit has been made, but before its announcement bauxite reserves in Hungary had been estimated at 250,000,000 tons. The deposits of the Vertesgebirge alone contain 120,000,000 tons and are mined by open-cut methods. Operating companies in this area are members of Bauxit Trust A. G., Zurich, and export most of the production to Germany. The small quantity used domestically is consumed by the alumina plant of the Bauxite Industry Co., a subsidiary of Bauxit Trust A. G., which supplies the 3,000-ton reduction plant at Csepel and the 2,000-ton reduction plant of the Hungarian General Coal Mining Co. at Tatabanya. Bauxit Trust A. G., in 1942 established a Hungarian subsidiary, Donautaler Tonerdeindustrie A. G., to produce alumina near one of the existing reduction plants. The capital of the new company, 35,000,000 pengo, is divided between the Hungarian state, Bauxit Trust A. G., and Aluminium Werke A. G., Berlin. Ungarische Bauxitgruben A. G. has started to construct its 20,000-ton alumina and 10,000-ton reduction plant at Ajka near Veszprem. To ensure sufficient power for these plants a power unit producing 250,000,000 kw.-hr. a year was erected. This expansion will cover domestic requirements of the metal and will leave a balance for export to other European countries without greatly affecting bauxite exports. The extent to which the Hungarian aluminum industry can be expanded depends on power sources. Since the return of northern Transylvania to Hungary, plans are said to be proceeding for generating more hydroelectric power in the Carpathians.

India.—Titaniferous bauxite has been located in Jashpur State, Chota Nagpur, India. The deposits, however, are far from rail facilities, and the nearest important town—Ranchi—is 100 miles eastward. Exploration has continued on the bauxite deposits in the Shevaroy Hills in Madras. The Aluminium Corporation of India, Ltd., an Indian-owned company, has a 6,000-ton alumina plant at Anupuagar near Asansol; bauxite deposits are nearby. A reduction plant was also started there several years ago, but owing to shortages of material it probably cannot be completed until after the war. Alumina production ceased after the production of 60 tons, and there appears to be no present prospect of its being resumed. The Aluminium Production Co. of India, Ltd., part British- and part Canadian-owned, has constructed a reduction plant at Alwaye, Travancore, which is reportedly producing at the rate of 1,500 tons annually. Capacity will be nearly doubled when additional power facilities have been installed. Alumina for the plant is being supplied from a pre-war stock pile which appears to be running low. Efforts to bring the alumina plant at Anupuagar back into production have been unsuccessful. The Aluminium Production Co. of India, Ltd., also owns and operates a fabricating plant at Calcutta which, with small additions,

Digitized by Google

can turn out 2 million pounds of strong alloy sheet a year. The necessary equipment will be installed by October 1943.

Ireland.—It is estimated that 100,000 tons of bauxite were shipped to Britain from Ireland in 1942. Bauxite occurs in commercial quantities in County Antrim in northeastern Ireland, where it is found in lenticles and irregular masses between two basaltic flows. The individual deposits appear to have no great extent or thickness.

Italy.—The alumina and aluminum facilities of Italy are extremely vulnerable to Allied air attacks since the last Axis forces have been swept from Tunisia. It is not unlikely that the Italian light-metal industries will be greatly impaired by Allied air activities, if indeed they have not already been seriously disrupted. The following list gives the location of the alumina and aluminum plants:

Company:	Alumina	Aluminum
Ind. Nazionale Alluminio	Porto Marghera, Bolzano	Bolzano.
Societa Italiano Allumina	Porto Marghera	
Societa Ind. Min. El. Chim. (S. I. M. E.)	Bussi	
Societa Alluminio Veneto Anonima (S. A. V. A.).	Porto Marghera	Porto Marghera.
Societa Nazionale Alluminio		Mori.
Societa Alluminio Italiano		Borgofranco.

Two more reduction works have been proposed—at Ferrara and Manteca.

Jamaica.—Extensive deposits of low-silica, high-iron bauxite were discovered in Jamaica in the latter half of 1942. Preliminary estimates indicate that over 10,000,000 tons of ore are available in small deposits of 30,000 to 60,000 tons each. The deposits occur as parts of an unconsolidated mantle overlying Tertiary limestone of probable Oligocene age and are found in two general areas—the first 15 miles northwest of Old Harbor and the second 20 miles north of Kingston. Overburden is said to be light or absent over much of the ore. Analyses indicate the following composition of the bauxite: 46 to 49 percent Al_2O_3, 1 to 3 percent SiO_2, and 15 to 20 percent Fe_2O_3. The deposits are said to be accessible by rail and motor road to deep water harbors. The Government has decreed under the Defense Regulations that any bauxite or other minerals worked on the island shall become the property of the King and disposed of in accordance with Government regulations. Canada is reported to be planning to import 500,000 tons from this source in 1943 if the deposits can be put into operation soon enough and if certain technical difficulties involving the high iron content can be solved.

Japan.—No official information is available on activity in the alumina and aluminum industries during 1942. Japan's goal in her Four-Year Plan for light-metal production was reported to have been 140,000 to 150,000 metric tons. Present information indicates that this goal was revised downward considerably, and 1942 production is estimated at 90,000 metric tons. Japan has ample reserves of bauxite at her command in the Netherlands East Indies on Bintan Island, Johore, and the Japanese-mandated Caroline Islands. Plans were to import 50,000 tons of high-grade bauxite from the Caroline Islands in 1941 and to step up the import rate from Johore, Unfederated Malay States (75,000 tons estimated for 1941). According to German reports deposits of aluminous material in Korea, Formosa, and Manchuria will be developed by the Japanese light-metal industry.

Deposits estimated at 10,000,000 tons in the Japanese-mandated Caroline Islands (Palao, Panope, Yap, Marakaro, and Garasumao)

Digitized by Google

have been developed by the Nanyo Aluminium Industry Co., a subsidiary of the Japanese South Seas Development Co. The ore averages 55 percent Al_2O_3, 1 percent SiO_2, and 11 percent Fe_2O_3.

Liberia.—The chief deposits of bauxite noted are in the Bulcama and Gisima Sections of the Lorma or Buzi country, at Massao, between Kpaia and Zorzor and between Zorzor and Pisabu.

Netherlands East Indies.—Bauxite produced on the island of Bintan opposite Singapore and the neighboring islands of Angkoet and Kojang has been under the control of the Japanese since early 1942. Deposits estimated at 10,000,000 to 20,000,000 tons had been developed by the Nederlandische Indische Bauxiet Exploitatie Maatschappij on these islands, averaging about 54 percent Al_2O_3, 2 to 3 percent SiO_2, and 13 percent Fe_2O_3. The principal workings are at Soengi Kolak on the Kidjang Strait. Before Japanese occupation, the bulk of the production since 1939 had been exported to Japan. It is estimated that, when fully exploited, the deposits of the Netherlands East Indies can supply the Japanese aluminum industry with 400,000 tons of bauxite annually.

Norway.—Before the German occupation of Norway, six plants with a total capacity of 22,000 tons of alumina and 36,000 tons of aluminum were in operation. Rated annual capacities of the reduction plants were as follows: Stangfjord (owned by British Aluminium Co.), 800 tons; Vigolands Brug (owned by British Aluminium Co.), 3,500; Eydehavn (owned by Det. Norske Nitrid A. S.), 9,500; Hoyanger (owned by Norske Aluminium Co.), 8,000; Haugvik (Glomfjord) (owned by International Aluminium Co.), 9,000. Alumina capacity was concentrated at the Hoyanger plant which had a 22,000-ton rated annual capacity. Norwegian aluminum production was to have been raised to approximately 130,000 tons through German controlled and financed expansions, but latest indications are that numerous difficulties have appeared to greatly impede this plan. Not the least of the troubles experienced by the Germans has been the vexing problem of supplying Norway with bauxite and alumina from France, Hungary, and Germany. Swedish information indicates that some of the aluminum works have been closed by the Germans because of the raw material situation. Reports of sabotage of German equipment for the reduction plants and alumina plants are numerous and suggest another reason for German retrenchment in the expansion program.

Spain.—A new aluminum plant with an annual capacity of 8,000 tons will be built by Empresa Electro-Mecanica de Cordoba, in Spain. At present Aluminio Español at Sabinania with an annual peak capacity of 1,100 metric tons is the only light metal producer in this country. Production at Aluminio Español remained at only about 70 percent of capacity during 1942 owing to a power shortage.

Surinam.—Virtually all of the 1,150,000 long tons of bauxite exported from Surinam (Netherlands Guiana) in 1942 by the Surinamsche Bauxite Maatschappij (subsidiary of Aluminum Co. of America) and the N. V. Billiton Maatschappij went to the United States and Canada.

Sweden.—The A. B. Svenska Aluminium Kompaniet, which raised its capital in 1941 to 2,000,000 Swedish kronor, has been granted a Government credit of 1,000,000 kronor to finance expansions of its works. Importation of alumina from Norway to the Månsbo reduction works near Avesta was stopped in 1941; to meet the alumina

Digitized by Google

shortage a subsidiary, A. B. Svenska Aloxidverken, was formed and has constructed a plant at Kubikenborg near Sundsvall for the manufacture of alumina from andalusite. This plant began operation in the spring of 1942; the capacity, estimated at 6,000 tons a year, can be increased if necessary.

Switzerland.—Owing to an acute shortage of copper Switzerland has had to rely more and more on aluminum as a substitute, particularly for electrical purposes. This has resulted in a 50-percent cut in the exports of aluminum and a drastic series of regulations on the domestic use of the metal, especially in containers, furniture, cooking utensils, and luxury items.

Unfederated Malay States: Johore.—The principal bauxite deposits in Malaya now under Japanese domination are in South and West Johore. Deposits have been developed at Bukit Pasir and Sri Medan, near Batu Pahat, by the Japanese Ishihare Sangyo K. K. and at Perigi Achih, 12 miles east of Johore Bahru, by Chinese enterprise. The ore is said to average 52 to 61 percent Al_2O_3, 5 to 15 percent Fe_2O_3, and 2 to 7 percent SiO_2. Ports of shipment for the bauxite are at Batu Pahat and Penggarand. Virtually the entire output has been shipped to Japan since the opening of the mines in 1936.

United Kingdom.—It is estimated that British aluminum production in 1942 increased about 40 percent over that in 1941. The bulk of British requirements, however, continue to be filled largely from Canada. The Open General License permitting the importation of bauxite and cryolite into the United Kingdom has been revoked by the Board of Trade; separate licenses were required for goods dispatched to the United Kingdom after November 9, 1942, and imported into the United Kingdom after January 9, 1943. Prices of 99 percent ingot remained pegged at £110 a ton delivered.

Yugoslavia.—Bauxite production in Dalmatia and Hercegovina is reported to have declined from 270,000 tons in the first 6 months of 1941 to 106,000 tons in the same period of 1942. The Croatian Aluminum Co. has been formed in Agram with a capital of 20,000,000 kroner to erect an alumina plant with an annual capacity of 100,000 tons and a reduction plant with a 50,000-ton annual capacity near Hum, Hercegovina. Domestic bauxite will be furnished from large deposits in the Karst region of Dalmatia and Hercegovina where bauxite containing 54 to 60 percent Al_2O_3 and 1 to 2 percent SiO_2 is reported to occur in large quantities.

SUMMARY

The year 1942 marked continuation of the forward movement of mercury production in the Western Hemisphere. The output of 50,846 flasks in the United States is the highest since 1882 and has been surpassed in only eight previous years. Mexico and Canada established new peak rates by substantial margins, Chile and Peru likewise contributed to the total, and development was under way in other areas. Mexico's output was 32,443 flasks compared with the previous record of 23,137 flasks in 1941, and Canada's totals were 13,470 and 7,057 flasks, respectively. As pointed out in previous issues of Minerals Yearbook, developments in Western Hemisphere sources since the war began have exceeded expectations and, coupled with restrictive consumption measures, have solved United Nations problems with regard to this strategic metal.

Reports emanating from Italy and Spain, normally the principal mercury-producing nations, indicate that those countries also attained record output. These claims cannot be verified, and it does not seem entirely reasonable to suppose that they are true in view of the curtailed world markets available to the two countries. On the other hand, stocks in Spain are reported to have gained sharply; if this report is reliable, it would tend to confirm the claim of high production rates. If actually establishing production records, Spain and Italy together could readily be recovering over 140,000 flasks of mercury annually.

Despite conservation measures, consumption in the United States was again higher than in any other year, surpassing the previous record (that in 1941) by 11 percent. Domestic production for the year could slightly more than take care of domestic needs, but requirements in the second half of the year exceeded production by 7 percent.

Under arrangements made by the Metals Reserve Co., imports of metal attained new heights in 1942—a total of 38,911 flasks. It is expected that imports of metal will gain notably in 1943 because of anticipated receipts of constant amounts from Mexico, of substan-

Digitized by Google

tially more than double the quantity obtained from Canada in 1942, and of 2,000 flasks from Chile.

As exports of mercury were under strict control, the happy balance between production and consumption in the United States in 1942 would have permitted a stock-pile accumulation of virtually all the metal imported had not a large demand for metal developed in the U. S. S. R. and an urgent order been placed in the United States. The demand was due in large part to occupation of the principal Russian source of mercury, the Donets Basin, by the German Army. From October 1942 through February 1943 exports to the U. S. S. R. were officially reported to have totaled nearly 21,000 flasks.

Salient statistics of the mercury industry in the United States, 1938–42

[Flasks of 76 pounds]

	1938	1939	1940	1941	1942
Production.....flasks	17,991	18,633	37,777	44,921	50,846
Number of producing mines	91	107	159	197	184
Average price per flask:					
New York	$75.47	$103.94	$176.87	$185.02	$196.35
London	$66.92	$88.26	$201.10	$194.20	$227.87
Imports for consumption:

Consumption.....flasks	[1] 19,600	[1] 20,900	26,800	44,800	49,700

[1] Apparent consumption.

Office of Price Administration.—Price-ceiling action taken by the Office of Price Administration in February 1942 was described in the Mercury chapter for 1941.

Metals Reserve Co.—In April, when permitted consumption lagged behind supplies available from domestic mines, the Metals Reserve Co. arranged to purchase surplus spot mercury from current domestic production at $192 a flask, f. o. b., New York. The program was enlarged in July to make it possible to dispose of metal at purchase depots established at many points throughout the country, and at that time it was extended conditionally through December 31, 1943. On March 30, 1943, the program was extended to December 31, 1944, with certain modifications regarding termination of purchases before that date. In projecting purchase agreements into the future, the Metals Reserve Co. recognized the premise that a sustained price, if at satisfactory levels, will insure greater production than will a rising price that may reverse itself at any moment.

Consumption restrictions.—Conservation Order M–78, issued January 23, 1942, restricted the use of mercury for certain purposes and discontinued its use for certain others; it was described in the Mercury chapter for 1941. In August 1942 the order was amended to add fireworks and preparations for film developing to the list of discontinued uses. The use of mercury for cosmetics or any preparation designed for bleaching the skin or removing freckles was cut to 30 percent.

Bureau of Mines and Geological Survey activities.—In continuing its search for strategic minerals, the Bureau of Mines investigated deposits of mercury in Idaho, Oregon, Nevada, California, and Alaska during the year.

Digitized by Google

An extensive area of mercury mineralization near the head of Cinnabar Creek in Valley County, Idaho, has been known since 1917. During 1941 and 1942 the Bureau of Mines completed 9,118 feet of diamond drilling on the Hermes, Annie Sell, and Pretty Maid claims, which resulted in the discovery of a large tonnage of commercial ore. It is estimated with reasonable assurance that underground operations upon a commercial basis may be continued for 3 to 5 years at a rate of about 300 flasks of mercury per month.

Early in 1942 the Bureau of Mines and the Geological Survey made preliminary examination of the Black Butte mine, south Lane County, Oreg. As a result of systematic sampling, which consisted of diamond drilling and extensive channel sampling on the 400-, 900-, and 1,100-foot mine levels, a large tonnage of low-grade ore was indicated.

Under a project called the Silver Spots Program, preliminary sampling was done on the following properties in Nevada: Reward Quicksilver mine, Mineral County; F and L Quicksilver mine, Esmeralda County; Mercury Mining Co., Nye County; Washington Hill property, Storey County; Thompson Quicksilver property, Nye County; B and B mine, Esmeralda County; Nevada Cinnabar mine, Nye County; Last Chance mine, Bottle Creek district; Rand mine, Ivanhoe district; Buckskin Peak, National district; and the Pershing Quicksilver mine, northeast of Lovelock. In Oregon the Bureau of Mines is conducting further exploration by churn drilling on the Bretz property in Malheur County.

The Guadalupe mine, 10 miles south of San Jose, Calif., is in one of the most productive mercury areas of the State. The Bureau of Mines has continued exploration in this area. The work has comprised trenching and test pitting of old dumps, as well as trenching and drilling of promising areas in search of new ore bodies; a substantial tonnage of low-grade ore is indicated.

Investigation and exploration continue on the mercury deposits in the Sleitmut area along the Kuskokwim River, Alaska. The Red Devil mine was explored during the summer and autumn of 1942, and a large tonnage of high-grade ore has been indicated. Other proved claims in the area include the Willis and Barometer and a number of small prospects where a potential reserve of 5- to 15-pound ore is available.

During 1942 the Geological Survey published reports on the mercury deposits of the Stayton [1] and Parkfield [2] districts, Calif.; Pike County, Ark.[3]; Wildhorse district, Nev.[4]; and Opalite district, Oreg. and Nev.[5] The Survey also issued general papers on the status of the industry[6] and concepts on the geology of mercury deposits in the United States.[7]

In California, field work was completed in the Guerneville district, Sonoma County, and the New Idria district, San Benito County.

Digitized by Google

A drilling project by the Bureau of Mines at New Idria, begun late in 1941, was completed. Geologic facts disclosed by drilling and by the Survey's detailed geologic mapping and interpretations are credited by the management as having led to the discovery of important new ore bodies. At the end of the year field work was in progress in the New Almaden district, Santa Clara County; Wilbur Springs district, Lake and Yolo Counties; Sulphur Bank district, Lake County; and the northwest and southeast parts of the Mayacmas district, Lake, Napa, and Sonoma Counties. A cooperative drilling and dump-sampling program was begun at the Guadalupe mine, New Almaden district, by the Geological Survey and Bureau of Mines. In Texas an exhaustive geologic study of all the mines in the Terlingua district was begun early in 1942 and was still in progress at the year end. In Oregon field work was completed on the Bonanza-Nonpareil and Horse Heaven districts, in Douglas and Jefferson Counties, respectively. Work was also in progress in the Meadows, Ochoco, and Blackbutte districts in Jackson, Crook, and Lane Counties. In Nevada, detailed geologic studies of the Pilot Mountains, Ivanhoe, and Relief (Antelope Springs) districts in Mineral, Elko, and Pershing Counties were completed. In addition to these larger districts, the Bureau of Mines and Geological Survey concluded a comprehensive sampling and mapping program that included nearly all the districts and isolated mines in the State and yielded concrete data on the reserves of commercial and marginal ores in Nevada. Supplementary reports were prepared on the only mercury-producing district in Washington and on the several mines in Arkansas. A detailed geologic study was made of the highly productive Hermes mine, Valley County, Idaho.

Preliminary investigations in Alaska were conducted at Decoursey Mountain, about 50 miles northwest of the Sleitmut area. In the Aleknagik area, Tikchik district, Southwestern Alaska, one promising prospect was investigated, and detailed but unsuccessful search was made for the bedrock sources of placer cinnabar in the Seventymile area in the Yukon region. In the Sleitmut area, Georgetown district, Southwestern Alaska, the Geological Survey continued investigations on five properties that were trenched and sampled by the Bureau of Mines. This work resulted in much more adequate determination of the surface outlines of several large ore bodies.

In Latin America detailed studies of the three most important mercury districts in Mexico—Nuevo Mercurio, Sain Alto, and Huahuaxtla—were made by the Geological Survey in the course of cooperative work with the Department of State. The work has been followed by significant increases in production. Study of an important prospect in Colombia was undertaken in cooperation with the Board of Economic Warfare.

Tests for mercury.—Since the outbreak of the present World War there have been many requests for information regarding specifications for mercury, tests to ascertain its purity, and other data along these lines. An article by Wichers [8] should be of interest in this connection.

[8] Wichers, Edw., Pure Mercury: Chem. and Eng. News, vol. 20, No. 17, September 10, 1942, pp. 1111-1112.

Digitized by Google

Wichers states—

Virgin mercury, that is, mercury as produced at the mines, usually has a bright, mirrorlike surface and is clean except for traces of scum or perhaps particles of rust or other foreign matter from dirty containers. If such mercury is filtered through a pinhole in a paper cone, a glass filtering crucible, or several thicknesses of finely woven cloth into a clean, dry glass vessel and thereupon retains a bright and clean appearance, one can be sure that it does not contain so much as one part per million of any base metal. Metals more noble than mercury, that is, silver, gold, and platinum group elements, are not disclosed, but virgin mercury is not likely to contain them in amounts as great as a few parts in a million. Reclaimed mercury is generally as clean as the virgin metal, but may contain more of the noble metals because it is not always subjected to distillation in the reclaiming process.

The statement that mercury which looks clean and does not show the behavior known as tailing is at least 99.9999 percent pure with respect to base metals may be challenged by many readers. It is indeed hard to believe that any commercial substance possesses such an exceptional degree of purity. But it can be demonstrated quite readily. To do so, drop about 0.5 mg. of tin foil into 100 grams of clean mercury in a small beaker or Erlenmeyer flask. Swirl the mercury around for a minute or so and observe the skin or crust that forms almost immediately. I think the observer will agree that the visible effect can be safely extrapolated to less than one part of tin in a million of mercury. Similar trials can be made with other base metals. The visible effects will not be exactly alike or appear equally rapidly, but they will be equally unmistakable.

PRICES

Monthly prices for mercury rose steadily throughout 1941 and into January 1942. Ceiling prices were established by the Office of Price Administration in February 1942; the details of the order (Price Schedule 93) were outlined in the Mercury chapter for 1941. Broadly, the prices ranged from $191 to $193 a flask, depending on the point of shipment. All other kinds and grades were to be sold at their normal differentials from the maximum prices established. Amendment 1 to Price Schedule 93 provided that, effective February 10 and until March 2, 1942, the schedule was not applicable to dealers who had mercury on hand or in transit on February 4 to meet contracts made before February 4. Press Release PM 2731, issued March 19, 1942, explained that the 2-percent premium allowed to dealers under the regulation could be split with another dealer or a broker but not with a producer if this would result in the producer obtaining more than the applicable maximum price. Amendment 1 to Revised Price Schedule 93 defined "mercury" as prime virgin mercury, redistilled mercury, reclaimed mercury, and all other kinds and grades of mercury. The amended schedule provided that, effective July 7, all kinds and grades of mercury sold in containers of 25 pounds or less should be sold and bought for not more than the normal differentials prevailing between October 1 and 15, 1941.

Under maximum price limitations the monthly quoted prices fell from $202.52 in January to $194.28 in June, remained at $194.43 for 3 months, and then advanced to $196 in November and December.

There is no evidence that any change has occurred in the average price for Spanish and Italian metal in what, for convenience, may be called the international market. As Germany was probably the principal consumer of mercury from these sources in 1942 and inasmuch as German methods of payment probably do not lend themselves to the restrictions of fixed prices, there is little question that the price indicated for Spanish and Italian metal was purely nominal.

Digitized by Google

The Control maximum prices for mercury in London were £48 15s. a bottle for over 1 bottle and less than 11 bottles and £48 for larger quantities, ex-sellers' premises in both cases. The prices were raised to £69 15s. and £69 in August, and they remained at these levels beyond the end of the year. Higher prices prevailed for lots under 1 bottle and for redistilled grades. There was speculation as to whether or not the advance in prices coincided with British purchased of Spanish metal.

Average monthly prices per flask (76 pounds) of mercury at New York and London and excess of London price over New York price, 1940–42

Month	1940			1941			1942		
	New York [1]	London [2]	Excess of London over New York	New York [1]	London [2]	Excess of London over New York	New York [1]	London [2]	Excess of London over New York

[1] Engineering and Mining Journal, New York.
[2] Mining Journal (London) prices in terms of American money through March 1940. Thereafter prices in terms of pounds sterling are converted to American money by using average rates of exchange recorded by Federal Reserve Board. Official prices, established early in May 1941, were £47 15s. to £48 15s. per flask until August 1942, when they were raised to £68 10s. to £69 15s.
[3] New York excess.

CONSUMPTION

Requirements for mercury gained in 1942 despite the restrictions placed on certain uses by the War Production Board, and a new high record rate of consumption was attained. Consumption was relatively stable in the first 3 quarters of the year, amounting to 10,300, 11,500, and 11,000 flasks. A 55-percent rise took place in the fourth quarter owing to some special orders for military purposes. Consumption in the 5-year period 1938–42 is shown in the following table, figures for 1938 and 1939 having been computed by the conventional method of adding production to imports and deducting exports, because of the absence of more precise information.

Data showing consumption of mercury by uses are shown in the second table following.

Supply of mercury in the United States, 1938–42, in flasks of 76 pounds

Year	Production	Imports for consumption	Exports	Consumption
1938	17,991	2,362	713	[1] 19,600
1939	18,633	3,499	1,208	[1] 20,900
1940	37,777	171	9,617	26,800
1941	44,921	7,740	2,590	44,800
1942	50,846	38,911	7,807	49,700

Mercury consumed in the United States in 1942, in flasks of 76 pounds

Use	Flasks [1]	Use	Flasks [1]
Pharmaceuticals	8,088	Electrical apparatus	4,550
Dental preparations	1,198	Industrial and control instruments	[2] 3,529
Fulminate:		Amalgamation	180
Munitions	4,146	General laboratory use	294
Blasting caps		Vermilion	215
Munitions other than fulminate	3,684	Felt manufacture	20
Agriculture	1,533	Redistilled	[2] 6,175
Antifouling paint	1,220	Other	[3] 9,103
As a catalyst or in the electrolytic preparation of—			[1] 49,700
Chlorine	549		
Caustic soda			
Acetic acid	1,410		
Other	1,843		

[1] The items are on a partial-coverage basis and do not add to the total, which has been increased to cover approximate total consumption.
[2] About half of the quantity shown under "Redistilled" was for use in industrial and control instruments.
[3] Of this total, 1,028 flasks were for a new chlorine-plant installation and to replace mercury-boiler leakages. It is deemed inadvisable at this time (May 1943) to divulge details covering 4,700 flasks.

Inasmuch as figures for 1941 were not obtained for the entire year upon the same basis, possibly the best means of comparing 1941 and 1942 data is to examine the total for 1942 in comparison with double the quantities reported for the latter half of 1941. Upon this basis the 1942 totals compare with 1941 as follows: Pharmaceuticals +51 percent, dental −2, fulminate +29, agriculture −61, vermilion −79, antifouling paint −10, felt manufacture −98, chlorine and caustic soda +77, acetic acid −15, other catalytic use −23, and amalgamation −44 percent. Production of redistilled mercury from virgin metal used 43 percent more metal in 1942 than twice the amount used in the latter half of 1941, and "other" uses were up well over 600 percent. Supplemental canvasses in 1941 and 1942 show that 50 percent or more of the metal redistilled is used to make industrial and control instruments, 16 percent for electrical apparatus, and 14 percent for dental purposes. A break-down of the quantities shown as "redistilled" in the table, therefore, would add substantially to the amounts used for these purposes. "Other" in 1942 includes mercury amounting to 4,700 flasks, the uses of which it is inexpedient to reveal at this time. Also reported under the "Other" class in 1942 are 1,028 flasks used in a new electrolytic chlorine-plant installation and in replacing metal leakages in mercury power boilers.

STOCKS

Inventories of mercury in the hands of consumers and dealers amounted to about 10,700 flasks at the end of 1942 compared with 12,400 at the end of 1941 and 14,100 at the end of 1940. On January 3, 1942, Metals Reserve Co. stocks totaled 5,408 flasks, and the Procurement Division of the Treasury Department held 2,050 flasks. On December 31, 1942, the Metals Reserve Co. had 17,416 flasks and the Procurement Division 9,994. Companies that use redistilled metal only held 2,400 flasks at the end of 1942 compared with 1,600 at the end of 1941. Stocks held by companies that report mine production monthly to the Bureau of Mines—about 95 percent of the total—were 1,377 flasks on December 31, 1942, compared with 439 flasks at the end of 1941.

REVIEW BY STATES

Under the stimulus of the highest annual price ever obtained and the assurance of a stable price, domestic producers gave a very good account of themselves in 1942; output was the highest since 1882. It is significant that the satisfactory quantity recovered was, for the most part, from mines whose names have been famous in mercury history for many years. The most important newcomer in 1942 was the Hermes mine (Idaho) of Bonanza Mines, Inc., just as the chief one in the recent past was the Bonanza mine (Oregon), operated by the same company.

The number of producing mines dropped from 197 in 1941 to 184 in 1942. The number in both years is very impressive in view of the fact that only about 20 mines [9] were active during the boom mercury period in the seventies.

Despite their excellent production record, producers were hampered by the same problems that beset other mining industries in 1942, particularly labor difficulties. Not only was the supply of labor insufficient, but available new workers were claimed to be very inferior. The inadequate labor supply impeded development work, and operators claimed this condition would doubtless have an early adverse effect on the rate of output.

Mercury produced in the United States, 1939–42, by States

Year and State	Producing mines	Flasks of 76 pounds	Value [1]
1939:			
Arkansas	5	364	$37,834
California	59	11,127	1,156,540
Nevada	25	828	86,062
Oregon	14	4,592	477,293
Arizona, Idaho, and Texas	4	1,722	178,985
	107	18,633	1,936,714
1940:			
Alaska	1	162	28,653
Arizona	6	740	130,884
Arkansas	10	1,159	204,992
California	70	18,629	3,294,911
Nevada	42	5,924	1,047,778
Oregon	23	9,043	1,599,436
Utah	1	53	9,374
Idaho, Texas, and Washington	6	2,067	365,590
	159	37,777	6,681,618
1941:			
Arizona	5	873	$161,522
Arkansas	19	2,012	372,260
California	87	25,714	4,757,604
Nevada	54	4,238	784,115
Oregon	21	9,032	1,671,101
Utah	1	19	3,515
Alaska, Idaho, Texas, and Washington	10	3,033	561,166
	197	44,921	8,311,283
1942:			
Arizona	7	701	137,641
Arkansas	16	2,392	469,669
California	85	29,906	5,872,043

Alaska, Idaho, Texas, Utah, and Washington	13	5,711	1,121,355
	184	50,846	9,983,612

[1] Value calculated at average price at New York.

The principal producing mines in 1942 were as follows:

Arizona—Maricopa County, Pine Mountain mine..

Arkansas—Clark County, Humphreys mine; Pike County, Arkansas Quicksilver group (Parker Hill and Gap Ridge).

California—Contra Costa County, Mount Diablo mine; Lake County, Great Western, Sulphur Bank, Abbott and Mirabel mines; Napa County, Knoxville and Oat Hill mines; San Benito County, Lea-Grant and New Idria mines; San Luis Obispo County, Oceanic and Klau mines; Santa Barbara County, Santa Ynez (Falcon) and Red Canyon (Red Rock) mines; Santa Clara County, New Almaden mine and Almaden dumps; Sonoma County, Socrates, Great Eastern, and Mount Jackson mines; Yolo County, Reed mine.

[9] Ross, C. P., Mercury Mining Today in the United States: Eng. and Min. Jour., vol. 143, No. 9, September 1942, p. 55.

Digitized by Google

Idaho—Valley County, Hermes mine; Washington County, Idaho Almaden mine.
Nevada—Humboldt County, Cordero and White Peak mines; Pershing County, Red Bird and Pershing mines.
Oregon—Douglas County, Bonanza mine; Jefferson County, Horse Heaven mine; Malheur County, Bretz mine.
Texas—Brewster County, Chisos and Big Bend and Texas Almaden mines; Presidio County, Fresno mine.

These 34 mines produced 89 percent of the United States total. The 33 most important mines produced 85 percent of the total in 1941, 29 produced 86 percent in 1940, and 16 produced 88 percent in 1939.

Several of the mines that were included in the group of 33 principal mines in 1941 were closed or virtually closed at the end of 1942. These were the Caddo, Contact, Idaho-Almaden, McAdoo group, Mount Tobin, Opalite, and Chisos. The Caddo and Opalite resumed production early in 1943. The Chisos has gone into bankruptcy, and no plans to reopen this famous old mine have been announced.

Before World War I the tenor of mercury ores treated in the United States averaged more than 10 pounds per ton or over 0.50 percent. The inclusion in the 1918 figures of a large quantity of low-grade material that was rejected before concentration at Sulphur Bank was partly responsible for the reduction in average grade to 6 pounds or 0.30 percent in 1918. In consideration of the sharply increased price paid for mercury in World War II, it is somewhat remarkable that the grade of ore treated has not fallen more rapidly. Dump material has been excluded insofar as possible from the grades shown for recent years, but separation of newly mined ore and dump material for many large mines (the New Idria is one of them) is not possible. The average grade indicated for 1942 was 0.25 percent (5-pound ore), compared with 0.26 percent (5.2-pound ore) in 1941, 0.31 percent (6.2-pound ore) in 1940, and 0.37 percent (7.4-pound ore) in 1939.

Alaska.—Output from Alaska came from Decoursey Mountain and Sleitmut areas, where geologic studies and drilling campaigns were carried on by the Geological Survey and the Bureau of Mines.

Arizona.—Production in Arizona declined from 873 flasks in 1941 to 701 flasks in 1942. The Pine Mountain, Ord, and Rattlesnake mines were the principal producing properties, and four others contributed to the total. Production was confined to Gila and Maricopa Counties.

Arkansas.—Fewer mines contributed to production in Arkansas in 1942 than in 1941, but a new record (by 19 percent) was established nonetheless. By far the largest producer was the Humphreys Gold Corporation property in Clark County. The Arkansas Quicksilver Mines, Inc., stood out in Pike County, and other large contributors in the State included the Caddo, Big Six, Superior, and U. S. Mercury.

The Humphreys Gold Corporation began development work in the summer of 1941 and in 1942 treated 18,758 tons of ore and recovered 1,176 flasks of mercury. In the final quarter of 1942 the production rate approximated 145 flasks a month.

California.—California increased its predominant position in mercury production in 1942, with an output of 29,906 flasks or 59 percent of the total, compared with 25,714 flasks or 57 percent of the total in 1941. All the California mines that ranked among the principal producers in 1941, except the Contact, were again prominent

Digitized by Google

in 1942, and the Abbott, Lea-Grant, Red Canyon (Red Rock), and Socrates joined the leaders. The Socrates mine was operated by the company that ran the Contact in 1941. An outstanding reason for the favorable California showing was the performance of the New Idria mine, whose output was more than double that of the next most important producer in the country in 1942 and was substantially more than equal to the combined total for the next three most important producers. The Sulphur Bank, New Idria, Klau, Mount Jackson, and Reed mines each produced nearly or more than 2,000 flasks in 1942.

Sixteen counties in California supplied some production in 1942, as follows: Colusa, Contra Costa, Fresno, Inyo, Kings, Lake, Napa, San Benito, San Luis Obispo, Santa Barbara, Santa Clara, Siskiyou, Sonoma, Stanislaus, Trinity, and Yolo.

At the Abbott mine, Lake County, the shaft was deepened 100 feet. The Mirabel mine, also in Lake County, produced 720 flasks of mercury from 7,317 tons of ore. Some production was reported for the Helen mine, which has since been taken over by the Anglo-American Mining Corporation, Ltd. Altogether, 10 mines in Lake County reported mercury production in 1942.

Production of the Twin Peaks Mining Co. was shifted from the Twin Peaks in 1941 to the Corona mine, Napa County, in 1942. A total of 4,915 tons of ore from the Corona mine was treated in the new plant at the adjacent Twin Peaks mine, and 203 flasks of mercury were produced. Zack Anderson (operating the Oat Hill Extension mine in the same county) reported the construction of a 40-ton mill which in May 1943 he anticipated would soon be in operation. Nine other properties in Napa County reported some production.

At the Lea-Grant mine, Panoche district, San Benito County, about 10,000 tons of ore were treated to recover 291 flasks of mercury. This mercury property is one of those in which the Marsman Co. of California became interested before the end of the year, the others being the Altoona in Trinity County, Calif., and the Reward in Mineral County, Nev. Greatly expanded operations were carried on by the New Idria Quicksilver Mining Co. at the New Idria mine in 1942, and production was materially higher. This mine sharply increased its lead over all others in the country, and further gains are anticipated in 1943. At the Panoche mine 11,303 tons of ore were treated and 197 flasks of mercury produced in a 4- by 64-foot rotary furnace. Fourteen other mines in the county were productive.

A new bank of steel condenser pipes was installed at the Oceanic mine, San Luis Obispo County. Ore from the Echo Butte (Little Bonanza group) was furnaced at the Oceanic plant. The shaft at the Klau mine in being deepened by 100 feet from the present 450-foot level, and a new level will be developed. At the Polar Star mine 90 tons of ore were treated in a retort and 63 flasks of mercury produced. This mine was under option to Lawrence Requa at the end of the year. Production came also from 6 other mines in the county.

The Red Canyon Mining Co. was superseded by the Cachuma Mining Co. in operation of the Red Rock mine, Santa Barbara County. Together they treated 10,450 tons of ore, which yielded 613 flasks of mercury. The Santa Ynez mine was again operated by Geo. H. Hall, who made an important output, and one other property in the county made a small contribution to the total.

Digitized by Google

In the early part of 1942 Aalders and Prather operated the Amenden dumps, Santa Clara County, which subsequently were operated by Sam Cohen. Cohen left the property before the end of the year owing to "litigation over alleged pollution of creek." The New Almaden mine has been opened to the 800-foot level through the Day tunnel. The Santa Rita shaft was reopened, and a 150-ton pocket was built on the 800-foot level. An important production, roughly three-fourths of which came from dumps, was made by this mine in 1942. The Guadalupe and seven other mines in Santa Clara County were also productive.

The Mount Jackson was the principal producing mine in Sonoma County in 1942. At the Great Eastern mine 605 flasks of mercury were recovered from 21,966 tons of ore. Sinking the shaft to the 500-foot level and crosscutting 320 feet northwest were hoped to develop considerable additional ore. The Culver-Baer produced 112 flasks from 263 tons of ore. Development work at the Socrates mine is reported to have promised additional ore reserves. The Contact mine was flooded in January 1942; its future is undetermined. Seven other mines in the county produced in 1942.

The Reed mine in Yolo County was one of the outstanding producers in the country as well as in the State.

Idaho.—The promise of another important producer in Idaho was brought to fruition in February 1942 when the Hermes mine became a substantial contributor. Monthly successive gains were made at this mine throughout the year, and for December 1942 it ranked as the second-largest producer in the country. This property is more than offsetting the loss of production from the Idaho-Almaden mine, which closed in December owing (according to the operator) to exhaustion of commercial ore.

Nevada.—Production in Nevada gained 23 percent, rising from 4,238 flasks in 1941 to 5,201 flasks in 1942, although it came from only 40 mines compared with 54. The noteworthy increase was due largely to expansion in production at the Cordero mine, principal producer in the State by a substantial margin in 1942 and one of the outstanding producing properties in the country. Productive operations were carried on in Elko, Esmeralda, Humboldt, Mineral, Nye, Pershing, and Storey Counties.

The Mount Tobin mine, Pershing County, an important producer in 1941, made an output during January and February only in 1942. The principal producing mine in the county was the Pershing, which had been inactive since 1930. A total of 18,041 tons of ore was treated and 855 flasks of mercury produced. The next largest was the Red Bird, where a Gould furnace was completed early in 1943. Williamson & Garteiz produced 127 flasks at the Roman mine, a newly developed property. Eight other mines produced in 1942.

Operations at the Cordero mine, Humboldt County, were described by Williston.[10] Greenan produced 343 flasks of mercury from 2,500 tons of ore at the White Peak mine and 4 flasks from 30 tons at the Red Ore. The McAdoo properties contributed little to the State total after January 1942, following the substantial amounts produced in 1941. Altogether nine mines in Humboldt County reported production.

[10] Williston, S. H., Mining Quicksilver in Nevada: Min. Cong. Jour., vol. 28, No. 11, November 1942, pp. 24–28.

Digitized by Google

Seven mines in Mineral County reported some output in 1942; the chief was the Reward mine.

Four mines in Nye County were productive in 1942. The Horse Canyon mine produced 6 flasks from 58 tons of ore and was abandoned.

Oregon.—Oregon experienced a sharp set-back in production in 1942, although maintaining its position as second-largest mercury-producing State. The 1942 total was 6,935 flasks compared with 9,032 in 1941, a drop of 23 percent, and Oregon's share of the United States total was 14 compared with 20 percent in 1941. An outstanding reason for the drop was the decline in output from the Bonanza, which, however, maintained its noteworthy lead in Oregon and held second place among the mines of the country. Other important producers were the Horse Heaven in Jefferson County and the Bretz in Malheur County. Clackamas, Crook, Harney, Jackson, Lake, and Lane Counties also reported some production.

Texas.—Production in Texas rose in 1942, but the year witnessed the passing into bankruptcy of the famous old Chisos mine, which was idle during the last several months. This mine had been in virtually continuous operation for 40 years. It is in the Terlingua region, which according to Ross [11] has had a total production exceeding 150,000 flasks and perhaps comprising nearly 200,000 flasks. The Chisos has contributed by far the greatest part of this total. Its output from 1902 or 1903 to the present ranks it historically as the fourth-largest producing mercury mine in the United States.

FOREIGN TRADE [12]

Under the stimulus of Metals Reserve Co. purchase agreements, imports of mercury in 1942 were the highest on record by a wide margin. Imports for consumption amounted to 38,911 flasks, considerably more than had been received in the 5-year period, 1937–41. The preponderant part—29,918 flasks—came from Mexico, 7,564 from Canada, and 1,409 from Chile; 20 flasks were credited to Nicaragua. The movement of mercury to the United States from normal sources was cut off in 1940. Mercury began to arrive from other sources in August 1941. In November and December 1941, 6,861 flasks were received out of the total imports for the year of 7,740 flasks. There was wide variation in the amounts of mercury received in 1942, by months, from a low of 1,791 flasks in August to a peak of 6,374 flasks in December. There was a difference of only 10 flasks between imports for consumption and general imports in 1942.

In addition to the mercury received from Mexico in the form of metal during 1942, antimony-mercury concentrates imported from that country yielded 1,050 flasks during the year compared with 1,300 each in 1941 and 1940. This latter class of imports is not shown separately in foreign trade statistics.

Mercury imported into the United States, 1938–42, by countries

Country	1938		1939		1940		1941		1942	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value
Canada							59,633	$130,468	574,888	$1,365,690
Chile									107,091	266,920
Germany									1	2
Hong Kong					3	$6				
Italy	84,454	$50,434	25,528	$29,818	228	316				
Mexico			42,745	61,313	9,698	13,681	520,692	1,171,752	2,273,739	5,088,709
Nicaragua									1,545	3,395
Spain	95,068	82,176	197,671	245,613	3,042	3,958	7,903	6,373		
	179,522	132,610	265,944	336,744	12,971	17,961	588,228	1,308,593	2,957,264	6,724,716

Imports of mercury compounds were virtually nonexistent during 1941 and 1942, as is shown by the table that follows. Early in 1940 the increased receipts of mercury compounds from Italy had been a minor threat, at least, to the domestic industry; all imports from Italy, both as metal and as compounds, ceased officially in 1940. A large shipment of metal and compounds in 1941, however, credited to Portugal and subsequently exported, has presented some food for speculation.

Mercury compounds imported for consumption in the United States, 1941–42

Compound	1941		1942	
	Pounds	Value	Pounds	Value
Chloride (mercurous) (calomel)	25	$83	1	$4
Mercury preparations (not specifically provided for)	24	140	12	132
Vermilion reds (containing quicksilver)	25	9	25	10
		232		146

Exports of mercury, under Government control since July 1940, dropped from 9,617 flasks in 1940 to 2,590 in 1941 and to only 249 in the first 9 months of 1942. The cutting off of most of the domestic mercury supplies of the U. S. S. R. by the German advance into the Donets area brought large orders from the U. S. S. R. for United States metal. In the final quarter of 1942, 7,461 flasks were recorded as having left the United States for the U. S. S. R. This record, however, lagged behind the actual movement of metal because a much greater quantity is known to have gone. The statistical lag was picked up in records for the early months of 1943. In the 5-month period October 1942 to February 1943, inclusive, mercury exports to the U. S. S. R. aggregated nearly 21,000 flasks. Total exports of mercury in 1942 aggregated 7,807 flasks. No country other than Russia received as much as 100 flasks of mercury from the United States in the year. Brazil received the second-largest amount—64 flasks—followed by Canada with 40, Venezuela with 32, Trinidad and Tobago with 30, and 4 dozen others with lesser amounts ranging down to 1 pound.

Mercury exported from the United States, 1938–42

Year	Pounds	Value	Year	Pounds	Value
1938	54,161	$50,184	1941	196,837	$470,903
1939	91,789	137,427	1942	593,311	1,519,227
1940	730,877	1,743,149			

The Commerce Department began to report exports of mercury salts separately in July 1941. For July 1 to August 31, 1941, totals only were given for mercury salts and compounds; they amounted to 3,213 pounds. No annual comparisons are available for the 1942 totals shown in the following table, but data for the last 4 months of 1941 are given in a parallel column.

Mercury salts exported from the United States in 1941 (September–December) and 1942, in pounds [1]

	1941 (Sept.–Dec.)	1942		1941 (Sept.–Dec.)	1942
Mercurous chloride (calomel)	6,976	22,844	Mercuric oxide (red and yellow)	4,261	9,495
Mercuric chloride (corrosive sublimate)	9,496	7,261	Mercuric sulfate		15
Mercuric fulminate	6,020	39,595	Mercuric sulfide	62	6
Mercuric nitrate	222	477	Other compounds	5,170	8,518

[1] See preceding paragraph.

WORLD PRODUCTION

Reliable data are not available on production in Spain and Italy, which dominate the world mercury industry in normal times. Increased rates of operations in Western Hemisphere countries, however, have been such that new world-record tonnages probably were established in 1941 and 1942, even if these two principal countries were operating considerably below capacity. What information has come out of Europe, however, has pointed to heavy mercury operations in both Spain and Italy. The recent gains in Western Hemisphere countries place the United States, Mexico, and Canada among the five most important producing nations and could even have pushed the United States temporarily into second place. The latter is considered a possibility but not a likelihood.

Algeria.—The invasion of North Africa in 1942 returned the resources of most of that area to the United Nations. The Ras-el-ma mine is in the Department of Constantine near the main road from Philippeville to Constantine, in the area where fighting has been in progress. A report from a source believed to be reliable places the output of this mine as 94 flasks in 1939 and 743 flasks in 1940. The ore is said to be of poor quality, containing less than 0.5 percent mercury, and production has been possible only in periods of high prices. In 1940 it was reported that the French hoped to obtain a large part of their annual normal consumption of 130 tons of metal from this mine.

Canada.—Production of mercury in Canada has risen precipitously since World War II began. It totaled 6 flasks in 1939, 2,024 in 1940, 7,057 in 1941, and 13,470 in 1942, and further increases are anticipated. All known occurrences of mercury in Canada are in British Columbia. The chapters on Mercury in the two previous issues of Minerals Yearbook pointed out that the development of the mercury deposit in the Pinchi Lake area, Central British Columbia, by the Consolidated Mining & Smelting Co. of Canada, Ltd., had given the British Empire its only important producer of mercury. The small initial plant installed by the company has been enlarged twice and is reported to be capable of handling 500 tons of ore daily. The ore

Digitized by Google

treated is reported to contain 0.5 to 0.75 percent mercury. The geology of the area has been described recently by Armstrong.[13] Considerable stimulus has been given to prospecting for mercury in British Columbia by the development of the Pinchi Lake deposit and by the increase in United Nations requirements for the metal. The Bralorne Mines, Ltd., largest gold producer in British Columbia, became interested in developing a mercury property late in 1942. The claims are on Silver Creek east of Takla Lake, in the Omineca mining district. Several flasks of mercury were produced in 1941 at the Red Eagle group on Yalakom River, 30 miles northwest of Lillooet.

Italy.—About the only report on Italy's mercury production in recent months placed the output of Stabilimento Minerario di Sieli, second-largest producer, at 40,000 flasks in 1941. This output, if matched by those of other producers, would mean a new high record for Italy. There is every reason to believe that Italy can produce over 70,000 flasks of mercury annually if there is need for it. With a surplus available from Spain and restricted markets for both countries, the need for record rates of output in the two countries could only mean that Axis requirements for mercury had expanded out of proportion to United Nations gains. Large accumulations of stocks would be the alternative, but with manpower at a premium in Italy it would seem strange to expend energy for accumulating excess stocks. According to the October 17, 1942, issue of Mining Journal (London) the State is now directly participating, through the Agrarian Bank and the Iri Holding Trust, respectively, in the two leading mercury companies, Siele and Monte Amiata. Italy is still a member of the Italo-Spanish International Cartel. Virtually the only foreign customer is Germany, which uses I. G. Farbenindustrie as its sole buying agent.

Mexico.—The expectation of a rapidly increasing production of mercury in Mexico was amply justified, as indicated by the total of 32,443 flasks for 1942 compared with 23,137 flasks for 1941 and 11,653 for 1940. The exports of 30,029 flasks were destined preponderantly to the United States, to which 29,113 flasks were shipped; 763 flasks went to Argentina, 120 to Brazil, 26 to Colombia, 6 to Chile, and 1 to Costa Rica. The War Production Board of the United States anticipated that approximately as much metal would be shipped to the United States in 1943 as in 1942. Mexico is playing a most important role in the solution of United Nations mercury problems.

New Zealand.—Investigations of cinnabar occurrences by the New Zealand Mines Department are reported to have indicated that a small but worth-while tonnage of high-grade ore may be developed. The deposit at Puhipuhi appears to be the only one capable of sustained production.

Peru.—A 20-ton Gould rotary furnace was installed at the Huancavelica mine in 1942. Two additional plants, with an expected combined daily capacity of 300 tons, were to be erected, but temporarily at least permit difficulties prevented their leaving the United States after they had been completed.

Spain.—Reports emanating from Germany (Hamburger Fremdenblatt), quoted in Metal Bulletin (London) of October 9, 1942, stated that Spain produced 85,523 flasks of mercury in 1941 and that 40,695

[13] Armstrong, J. E., Geology of the Pinchi Lake Mercury Belt, British Columbia: Canadian Min. and Met. Bull. 362, June 1942, pp. 311-323.

Digitized by Google

flasks were sold (of which 706 were for use at home and 39,989 for export); also that stocks at the Almaden mine at the beginning of 1942 totaled 66,000 flasks. If this report is true, production was 18 percent higher in 1941 than in 1927 and therefore was at a new all-time record rate. It is rather difficult to understand, however, why an effort was made to produce a record quantity in view of the fact that the war has caused a shrinkage in Spanish markets. Metal is reliably reported to have moved from Spain to Germany in large quantities in the early part of 1941. It is only logical to assume, however, that with Italy able to supply much more mercury than is ordinarily required in Germany, purchases of Spanish metal in Germany would drop to insignificant proportions. Political considerations, of course, could affect German policy in this connection. In explanation of the high rate of production in Spain, an article in Engineering and Mining Journal of May 1942 says—

> * * * By law, in Spain, no workman of regular crew may be laid off without long advance notice. Hence, either production must go on at a minimum rate, or payroll with no output must be maintained. It is for this reason that such a huge inventory has been accumulated * * *.

The cartel price had an adverse effect on sales to the United Kingdom. Purchases have been made in the United Kingdom since the war started, however, and in August 1942 the London price was raised from £48 to £69, the latter figure corresponding more closely with the cartel price.

Union of South Africa.—Output in the Union is increasing steadily according to Preller.[14] In the chapter on Mercury in Minerals Yearbook, 1941, it was pointed out that some anxiety was felt in that country regarding supplies of mercury. Preller states that production at Monarch Kop in 1942 had fallen not far short of requirements in the Union and that an excess over local consumption might result in 1943. The cinnabar at Monarch Kop occurs with lenticles of quartz and crystalline carbonate in chloride-carbonate schists through a thickness of 15 to 20 feet in places. The deposit is reported to show great promise as far as consistency and extent are concerned.

U. S. S. R.—The principal producing area in the U. S. S. R. has been the Donets Basin. Output from this source has been lost temporarily owing to German occupation of the territory. Production is now coming from other localities in Russia, notably from Kirghiz which started to produce before the war. Exploratory work in connection with mercury recently has been widespread, stretching from the Donets area to Eastern Siberia. Despite the efforts to increase output of this strategic metal, Russia depends largely on imports from China and other United Nations. Chinese metal has been going to Russia for some time, and late in 1942 large quantities of mercury began moving to Russia from the United States. Exports from the United States were largely "reexports" or metal imported from Mexico, Canada, and Chile, although domestic metal made up part of the total. According to the Department of Commerce, shipments to Russia from the United States totaled nearly 21,000 flasks from October 1942 through February 1943.

GENERAL SUMMARY

An abrupt transition from an economy of abundance in tin to one of dearth marked the year 1942. In 4 months after the attack on Pearl Harbor the Japanese had added two-thirds of the world's tin resources and nearly three-quarters of the smelter capacity to the strategic metals assets of the Axis associates. There remained to what became known after January 1, 1942, as the United Nations a potential annual supply of only 80,000 to 90,000 long tons of virgin tin, a volume little greater than that consumed in the United States alone in 1940 (72,324 long tons) and much less than the 103,086 long tons used in the peak year 1941.

The terrific shock of the Japanese blitzkrieg in Malaya and in the Netherlands East Indies on the tin-consumption habits of the United States was fortunately cushioned by defensive measures undertaken coincident with the growth of an understanding of Japan's East Asia policies. Foremost among these measures were the inception of a stock-piling program and provisions for domestic smelting, with the acquisition of ore supplies.

At the close of 1941 there were on hand 45,572 tons of ore and concentrates containing over 23,000 long tons of tin. Total stocks, excluding the 7,433 tons held by the Navy and Procurement Division, contained over 126,000 tons of tin as metal and in concentrates. Although 1942 opened with an abnormally large, immediately available stock, prospective future supplies were limited essentially to about one-half of Bolivia's raw-material output and to the Belgian Congo's metal—sources that at best could furnish scarcely 40 percent of the virgin tin consumed in 1941. Drastic steps thus had to be taken to maintain a safe position in tin. Immediate and severe restrictions were placed upon use; broad substitution programs and expanded reclamation schemes were instituted and were frequently revised or amended during the year but always in the direction of a tightening control. Exports, which were already governed by the

Digitized by Google

Export Control Act of July 1940, were likewise subjected to further restrictions.

As a result of control and conservation, nonessential uses were almost abandoned, there was widespread degradation in bearing metals, and a transition was being effected in the major consumption areas of solder and tin plate to tinless solders and to thin electrodeposited, chemically treated, and black plates, accompanied by enforced shrinkage in volumes. Although the effect of the shift to electrolytic tin plate, with its estimated 60-percent decrease in tin used compared with hot-dipped plate, was slight because of the difficulty in obtaining and installing a vast amount of new and specialized equipment, tin consumption showed an uninterrupted monthly decline ranging from 7,500 tons in January to 3,200 tons in December 1942, with the year's virgin tin consumption reduced to 56,000 tons or less than 55 percent of that used in 1941.

Imports of metal were at the lowest point in more than 20 years and were only 18 percent of the 1941 tonnage; although the total tin content of the ores imported increased by about 9 percent, the over-all drop totaled 66 percent. Of the 57,000 tons received, about 15,000 tons of metal and 8,000 tons (tin content) of ore belatedly arrived from Malaya, the Netherlands East Indies, and China. Total stocks declined only 1.5 percent to the equivalent of 3¼ years' supply at the indicated consumption rate in the last quarter of 1942.

Salient statistics for tin in the United States, 1925–29 (average) and 1938–42

[1] Subject to revision.
[2] Including tin content of ores used direct to make alloys.
[3] Figures for 1938–41 cover foreign only; domestic not separately recorded.
[4] Less than 1 ton.
[5] Ceiling price 52 cents.

Maintenance of this relatively comfortable position—one that appears to have been paralleled in Great Britain—appears unlikely. A lengthy campaign for the recovery and rehabilitation of Far Eastern mines and reduction works is indicated. China is essentially isolated; production in Bolivia and Nigeria declined below 1941 levels and was not offset by the increase from the Belgian Congo, with little likelihood that an appreciable net increase may be expected in 1943, with all shipments subject to the shortage of bottoms and German submarine warfare. In Great Britain consumption is said to be held at the "austerity" level that lies at approximately 14,000 tons. It has been

Digitized by Google

estimated that in the immediate pre-war years the U. S. S. R. apparently used about 15,000 tons annually, but its current actual needs are materially greater. (See section on Foreign Trade.) In the United States the principal remaining area of economy, which should be reached in 1943, lies in the substitution of thin electrodeposited and tinless plates for hot-dipped plate. However, the degree of substitution is limited by numerous factors, including the nature of the goods to be packed and the probable increasing volumes of plate and processed-food containers needed for Lend-Lease shipments and for overseas use, both military and civilian, all of which require higher-grade protective coatings than that serviceable for domestic use. With a probable consumption of around 50,000 tons in 1943 in this country, the total needs of the United States, Great Britain, and the U. S. S. R. seemingly exceed the maximum output of the United Nations that have an exportable surplus. Thus there may be no relaxation of controls; rather, more stringent enforcement and extensions are to be expected.

Controlled sales prices were effective throughout the year, in the United States at 52 cents per pound New York for Straits tin or equivalent grade, and in the United Kingdom at £275 for standard tin delivered buyers' works. Tin consumers have benefited greatly by these price-fixing policies. Under the revised contract with Bolivian producers the purchase price was set at 60 cents per pound at export ports, which has been estimated to be 62 cents or more New York. This represents an apparent subsidy of 10 cents per pound or approximately $3,500,000 on the pig tin produced in the United States in 1942 or over $5,150,000 based on imports from Bolivia.

GOVERNMENT ORE PURCHASES

No sizable ore-purchasing contracts were concluded in 1942, but deliveries under earlier agreements continued. (See Foreign Trade—Imports.) One cargo believed to have contained about 2,000 tons of tin was lost en route to the United States in May.

The original contract of November 4, 1940, with Bolivian producers was based upon a price of 48½ cents, c. i. f. New York, and contained a provision for price review at stated intervals. Pursuant thereto negotiations were undertaken, and as of June 30, 1942, the signing of an amended contract retroactive to January 1, effective through June 30, 1943, was announced. The price was raised to 60 cents per pound contained tin f. o. b. Chilean or Peruvian ports—an increase of nearly 30 percent, since freight and insurance fell to the account of the buyer. The contract also called for a minimum delivery of 1,500 tons per month and a maximum of 2,500 tons (tin content). Up to 20 percent of the shipments could range from 18 to 35 percent tin. Smelting charges were set at $32.25, $31.60, and $30.40 per ton for the three classes of acceptable materials, with a sliding scale of deductions for impurities.

GOVERNMENT TIN SMELTER

Construction of the Federally financed tin smelter was begun in October 1941, and the first metal was poured April 5, 1942. The original plans called for capacity to treat the portion of Bolivian ores made available to the United States, that is, about 50,000 tons per

Digitized by Google

year or 18,000 tons of tin. Subsequent enlargements raised its capacity to about 90,000 tons or enough to treat the entire United Nations ore supply. The total cost of the plant has been reported to be about $6,300,000.

A description of the smelter and methods of ore treatment, accompanied by flow sheets, has been published.[1] The plant was designed to treat complex, low-grade as well as high-grade ores. Over-all recovery is said to exceed 98 percent. Two grades of tin are produced: Longhorn 3 Star, over 99.8 percent pure, and Longhorn 2 Star, which on a selling-price basis would assay between 99.00 and 99.75 percent.

In the metal trade here and abroad there has been much speculation concerning the post-war position of the Texas City smelter and an inclination to believe that it will remain a competitive factor in world trade. Aside from any long-term ore-purchasing contract that may be made before the war's termination and the freedom of access to raw materials proposed under the Atlantic Charter, it occupies a strategic position geographically and with respect to fuel, hydrochloric acid, and power (somewhat offset, to be sure, by high unit labor costs). The additional advantages of a most modern and extremely flexible plant plus the accrued knowledge of efficient reduction processes for complex and off-grade ores endow the operating organization with considerable bargaining strength, especially in the low-grade or refractory ore field.

CONSERVATION

The loss of the major supply sources before a stock pile of adequate dimensions could be accumulated necessitated the application of rigorous use controls, with corollary substitution and reclamation programs. These orders frequently were modified or amended to effect closer regulation and were extended through auxiliary limitation and conservation orders to stop lesser loopholes in the restraining program.

The final effect of the multitudinous orders cannot yet be evaluated exactly, but as shown under Consumption by Uses the program was highly effective in 1942. Estimates of potential savings indicated that roughly one-half would be derived from nearly complete prohibition of use, such as for foil and collapsible tubes, and the remainder through down-grading in tin content and substitutions. In the last field the displacement of metal by glass containers, largely as a result of the limitation placed on use of steel, was the most important factor and has been estimated to have been as great as 30 percent. Fiber containers have found increasing use and to some extent are expected to remain competitive in peacetime. Ordinary black plate cannot be expected to take the place of much tin plate because it lacks corrosion resistance, but chemically treated (bonderized) black plate, enameled or lacquered, is claimed to be suitable for many general line and some sanitary cans. It is believed that it may take care of more than one-eighth of the total container production in 1943.[2] However, that product is still in an experimental stage, and its future application will depend in large measure on the availability of tin that has demonstrated value in food preservation. Only one plant was known to be operating in 1941, but it was expected that 18 to 20 bonderizing lines would be built in 1942.

Digitized by Google

In the degradation area, the reduction in tin content of solders, extending to the tinless lead-silver solders, in bronzes and bearing and terne metals have effected pronounced economies in tin use. The greatest saving possibility in this field, owing to the huge quantities involved, lies in the reduction of thickness in tin-plate coating. By February 1942 this had been reduced from the customary 1.5 pounds per base box to the lowest practicable hot-dip limit of 1.25 pounds, with an appreciable resultant saving. However, the need of heavily coated tin plate for the large proportion of food packs intended for the armed forces and Lend-Lease so restricted the amount of tin available that it became imperative to employ an alternative method of coating that could provide the quantity of tin plate necessary for other consumers.

A metal coating of virtually any desired thickness can be electrodeposited. This method is not new, but its commercial application to tin plating on a plant scale is recent [3] and was still small in 1941 and 1942, amounting to only 2.85 and 3.4 percent, respectively, of standard coke tin-plate tonnage. To meet the expected demand—estimated to be as much as 40 percent of current tin-plate requirements—it was hoped to construct 26 or 27 electrolytic lines in 1942, but actual completion fell far behind the planned schedule owing to the inability to obtain the vast amounts of electric equipment and control apparatus needed.

Electrolytic tin plate having only 0.1 pound per base box has been made experimentally and may serve for some purposes. In general, a coating weight of 0.5 pound is required for many packs under conservation regulations. There is a tendency, however, to believe that a heavier plate, 0.75 to 1.0 pound, eventually will be found more satisfactory or necessary for the widest application.

The future economic position of thinly coated tin plate is not yet clear, as some time must elapse before it can be tested fully in practice. For numerous goods it would afford ample protection, and according to reports it can be soldered as well as the standard hot-dipped plate. In that respect and because it will withstand deformation—deep drawing or forming—without injury it is materially superior to bonderized lacquered plate and seemingly can be fabricated at much greater speeds. (See Review by Countries—Germany.) At present the 0.5-pound electrolytic plate has a price differential of 50 cents per base box in its favor. These and other advantages point to partial displacement of standard tin plate and chemically treated plate that some authorities have estimated as high as 40 to 50 percent.

INVESTIGATION OF DOMESTIC TIN DEPOSITS

Continuing their endeavors to find workable tin deposits in the United States and Alaska, the Bureau of Mines and the Geological Survey extended earlier explorations, undertook several new projects, and published eight reports.

The Geological Survey made reconnaissance surveys in Alabama of pegmatites and in the Black Hills of South Dakota. Reports on these projects are not yet available. A field study of the Temescal district, Riverside County, Calif., was concluded. It is understood

[3] The first plant for the plating of wide, continuous strip was erected by the Crucible Steel Co. at its Midland (Pa.) works in 1936. Shortly thereafter the Carnegie-Illinois Steel Co. installed an electrotinning line at Gary, Ind., and in 1941 the Crown Cork & Seal Co. put a line into operation at Baltimore, Md.

Digitized by Google

that the Metals Reserve Co. has approved the installation of machinery and that material for milling tests would be taken from open pits in the spring of 1943. Detailed studies of the Gorman district, northwest of Los Angeles, and mapping at Cima, San Bernardino County, were carried out.

The Bureau of Mines and Geological Survey continued field studies on the tin resources of New Mexico. Preliminary reports indicate that some very small placer areas can probably be mined under present conditions but that the lode deposits are not sufficiently rich to be developed economically at this time. In March 1943 the Geological Survey published an areal geological map of the tin district in the Black Range in Catron and Sierra Counties, N. Mex., accompanied by a descriptive text prepared by Fries and Butler.

The Bureau of Mines conducted an exploration project that included drifting, crosscutting, and long-hole drilling at the Majuba Hill mine in Pershing County, Nev., and the Geological Survey made a detailed study of the mine.

In Alaska, Geological Survey geologists studied and mapped tin placers in the Tozimoran, Morelock Creek, and Ruby-Long areas, all lying in the Yukon Basin region of the interior a considerable distance west of Fairbanks. The Bureau of Mines examined tin placers in the Buck-Creek-Potato Mountain areas at Cape Mountain near Tin City. In the Manley Hot Springs area near the junction of the Yukon and Tanana Rivers the Bureau of Mines examined tailings from early gold-placer operations. In July 1942 the Bureau of Mines began explorations in the Lost River tin area in western Seward Peninsula. The Geological Survey, in conjunction with Bureau of Mines engineers, made a supplementary examination. The Bureau's preliminary sampling in this area has indicated a large tonnage of low-grade tin-tungsten ore of about 0.8 percent tin and 0.25 percent WO_3. This district appears to offer the best possibilities for domestic tin production; however, immediate development will depend on the ability to obtain clearance and ship space for transporting materials and supplies to this remote area. The Bureau of Mines plans further exploration.

DOMESTIC PRODUCTION

MINE OUTPUT

Domestic tin production dropped to 6.3 long tons, the lowest point in 9 years, owing to virtually complete loss of Alaskan output following commercial exhaustion of the Tin City placers. No lode tin was obtained in 1942.

The prospect for a sizable increase in the immediate future is far from bright. The total recorded mine production from the United States and Alaska in the past one-third of a century amounted only to 1,521 tons valued at about $1,666,000,[4] of which nearly 95 percent was furnished by Alaska. No consequential deposits were brought to light in the United States proper. Alaska has a small potential; but that, as far as is now known, is largely concentrated in low-grade and narrow lodes that require much machinery and equipment for large-scale production and concentration.

[4] Data for 1910–38, inclusive, were published in Minerals Yearbook, 1939, p. 679.

[2] Subject to revision.

SMELTER OUTPUT

The major event of the year from a production standpoint was the revival of large-scale domestic smelting that had been dormant since 1923. Output for the first full month of operation (May) of the Longhorn smelter was 1,246 long tons, and it rose almost uninterruptedly to 2,343 tons in December, with a total for 1942 of 15,696 long tons, a little (65 tons) below the peak smelter output in 1920. Based upon the 2-month average for November–December 1942, however, production was at the annual rate of 28,000 tons. Shipments were 1,403 long tons. The 3 Star grade has received a favorable reception; the second or 2 Star grade, which is believed to assay about 99.5 percent tin, came on the market late in 1942.

Production from ores by privately owned smelters dropped 74 percent from the 1941 figure. Of the 472 long tons output, 243 tons (1941, 502 tons) appeared as pig tin and 229 tons (1941, 1,337 tons) in alloy form, principally solder. Companies reporting production in 1942 were the American Metal Co., American Smelting & Refining Co., Nassau Smelting & Refining Co., Phelps Dodge Refining Corporation, and Vulcan Detinning Co.

In 1942 one-quarter of the ore imports were from the Netherlands East Indies, which usually produced concentrates of approximately 72 percent tin content. Nearly all the remainder originated in Bolivia. The grade of these supplies is not available, but incomplete data on gross weight and tin content of the mine production give indicated grades for 1940, 1941, and 1942 of 51, 41, and 40 percent, respectively.[5]

SECONDARY TIN

Total recovery of secondary tin declined about 10 percent from the record high level of 1941 to 33,900 long tons in 1942. Most of the so-called secondary tin (80 percent or more) is contained in copper-tin or lead-base alloys, from which it is rarely extracted as metal but remains as a circulating constituent. In addition to the decline in volume of re-treated materials, down-grading with respect to tin content in important alloys, such as solders, bearing metals, and bronzes, as a consequence of the conservation program, was beginning to affect the quantity of tin recovered. The principal source of metal and of tin chemicals is clean tin-plate clippings and used containers

[5] These figures slightly understate the quality because the weight of sacks is included in the gross weight. The Metal Industry (London) of February 26, 1943, on the basis of grades of concentrates shipped in November 1942 and on the assumption that all the Patino-group product was delivered to England arrived at an average of about 36 percent for shipments to the United States.

Digitized by Google

treated at detinning plants. The quantity of tin reclaimed as metal by detinners rose about 4 percent to a new high of 4,700 long tons, but the tin content of chemicals declined 79 percent to a low of little more than 200 tons.

The collection of prepared, used tin cans has been highly disappointing—variously estimated to have been between a quarter and a third of the potential—but the amount of tin recovered jumped nearly 800 percent above the 1941 output of about 60 tons to over 530 tons in 1942. Although the weight of clippings treated dropped more than 15 percent from the 1941 level—a reflection of the restrictions placed on tin-plate manufacture—the amount of tin recovered receded only 6 percent to a little more than 4,160 long tons owing principally to the pronounced shift from chemical production as noted above. Further details will be found in the chapter on Secondary Metals—Nonferrous.

Secondary tin recovered in the United States, 1925–29 (average) and 1938–42

Year	Tin recovered at detinning plants			Tin recovered from all sources			
	As metal (long tons)	In chemicals (long tons)	Total (long tons)	As metal (long tons)	In alloys and chemicals (long tons)	Total	
						Long tons	Value
1925–29 (average)	900	2,000	2,900	7,500	23,100	30,600	$38,034,120
1938	2,200	1,300	3,500	4,300	16,700	21,000	19,284,600
1939	3,600	600	4,200	4,000	22,000	26,000	29,276,600
1940	3,700	600	4,300	4,500	25,200	29,700	33,102,400
1941	4,500	950	5,450	5,300	32,200	37,500	43,722,700
1942	4,700	200	4,900	5,200	28,700	33,900	39,434,700

CONSUMPTION

APPARENT CONSUMPTION

The apparent consumption of primary tin, calculated by adding smelter production to net imports, was 42,005 long tons in 1942 or roughly 30 percent of the 1941 record of 141,618 long tons. This method of reckoning consumption excludes all changes in metal stocks held by consumers and the Government, and in times of extraordinary movement, such as the period 1940–42, may present a highly distorted picture. Frequently, however, basic data for more accurate calculation are not available, hence apparent consumption statistics offer the only indicator of long-term trends. These data for 1910–38 were published in the Minerals Yearbook, 1939 (p. 680); those for 1938–42 follow.

Apparent consumption of virgin tin, 1938–42, in long tons

1938	49,494	1941	141,618
1939	67,997	1942	42,005
1940	123,537		

CONSUMPTION BY USES

The following tables show actual consumption of primary and secondary tin, as reported to the Bureau of Mines. Pronounced changes in the tin-consumption pattern arose during 1942 as a consequence of the metal's highly critical status. Tin plate retained its normal premier position, accounting for 51 percent of the consumption of virgin tin, although there was an absolute drop of 36 percent from

Digitized by Google

the 1941 record level. Solder that usually held second place, using about half as much tin (primary plus secondary) as tin plate, was displaced by bronze and brass that used 47 percent more primary and twice as much total tin as solder, with a new peak total consumption almost equal that of tin plate. Among the reasons for this shift were the recession in demand that followed cessation of automobile production at the end of 1941, the progressive down-grading in tin content in solders, and the continued expansion of armament output with the tremendous increase in the launchings of naval and merchant ships. Tin used for babbitt declined 42 percent, largely because of the decrease of approximately one-third in white-base antifriction-metals production and the substitution of lead-base for high-tin babbitts. The virtual elimination of tin for foil brought about a saving of approximately 3,700 tons or 87 percent of the 1941 use. Restrictions on the use of tin for collapsible tubes resulted in a drop of 75 percent compared with 1941. These uses in the immediate pre-war period, 1937–40, accounted for about 88 percent of virgin-tin consumption that averaged nearly 65,000 tons a year. In 1942 there was a relative rise to 91 percent but an absolute decline of 13,800 tons. A pronounced downward trend was in evidence in the remaining use fields, especially in tin oxide, galvanizing, and white metal, in which the enforced savings were roughly 90 percent of the preceding year's use. Changes in the application of secondary tin were much less pronounced, although alloy down-grading increased the proportions contained in solder, bronze, and brass. Secondary tin consumption in 1942 was 29,400 tons or 93 percent of that for the previous year, while the ratio of secondary to primary rose to 52 percent compared with the 24-percent peacetime (1935–39) average for which data are available.

Consumption of primary and secondary tin in the United States, 1938–42, in long tons

	1938	1939	1940	1941	1942
Stocks on hand January 1	25,984	25,260	29,025	56,999	[3] 67,421
Net receipts during year [1]	61,431	89,018	128,030	149,123	65,568
Available supply	87,415	114,278	157,055	206,122	132,989
Stocks on hand December 31	25,260	29,025	56,999	[3] 67,421	[3] 43,853
Total processed during year	62,155	85,253	100,056	138,701	89,136
Intercompany transactions in scrap (tin content)	2,122	2,390	2,190	2,936	2,547
Total consumed in manufacturing	60,033	82,863	97,866	135,765	86,589
Plant losses	[2] 259	435	712	1,070	902
Tin content of manufactured products	59,774	82,428	97,154	134,695	85,687
Primary	48,116	[4] 66,583	[4] 72,324	[4] 103,086	56,288
Secondary	11,658	15,845	24,830	31,609	29,399

[1] 1938: Primary, 50,052; secondary, 1,983; terne, 787; scrap, 8,609. 1939: Primary, 70,732; secondary, 4,976; terne, 1,171; scrap, 12,139. 1940: Primary, 98,125; secondary, 5,409; terne, 1,086; scrap, 23,410. 1941: Primary, 114,281; secondary, 6,879; terne, 1,851; scrap, 26,112; 1942: Primary, 33,126; secondary, 5,096; terne, 405; scrap, 26,941.
[2] Not including 2,700 tons in transit or in warehouses.
[3] Not including 78 tons in transit.
[4] Includes small tonnage of secondary pig tin.

The total tonnage of primary and secondary tin used was reduced 49,000 tons or 36 percent from the 1941 high and was only 4 percent above the 1937–40 average. The true effectiveness of the conservation program is to be evaluated, however, by the economy in virgin metal. Primary tin consumption was 47,000 tons or 45 percent less

than in 1941 and nearly 13 percent below the 1937–40 average. In Great Britain the savings goal had been set at about 50 percent of the average pre-war use, which probably has been reached, and Germany appears to have made greater reductions. Commenting on the United Nations tin situation, The Metal Bulletin of London said [6] "The fact is that tin is of far less importance as a war metal than anybody had suspected" and, with respect to common use, "to a greater extent than was realized at the time, the use of tin was of the nature of a semi-luxury." The future of tin is not clear, but many of the displacements and substitutions forced upon the consuming industries by the exigencies of war, as indicated in the foregoing paragraphs, are likely to persist in the future.

FOREIGN TRADE [7]

The main constituents of the foreign trade of the United States until 1940 were the imports of pig tin and the exports of tin plate. In that year, owing to the newly initiated stock-piling program, metal imports reached a new high, which was then exceeded by the record importation of 141,000 tons in 1941. Total metal imports were 26,000 tons in 1942; but of that—the lowest figure in this century except in 1921 (24,197 long tons)—nearly 60 percent represented arrivals from Far Eastern countries that were cut off as sources early in the year.

In 1924–39, inclusive, the tin content of imported ores and concentrates had an annual range from less than 1 ton to 500 tons, with an average of only 150 tons. Ore imports attained an all-time record of 31,212 tons in 1942. Bolivia was the principal point of origin, furnishing 23,029 long tons or nearly 5 percent above its 1941 volume. Important because of the high quality and, for the near future, irreplaceable large share (26 percent) in imports were arrivals of 7,977 tons from the Netherlands East Indies. French Cameroun again supplied a small quantity—161 tons—and receipts from Mexico dropped to 45 long tons.

The major tin-export item of the United States, as usual, was tin plate (including terneplate). In 1942 an all-time export record of 594,000 tons was set up—the United States became essentially the sole anti-Axis-world supplier.

Foreign trade of the United States in tin and tin concentrates, 1938–42

Year	Imports				Exports of tin (metal)[1] (long tons)
	Tin (metal)		Tin concentrates (tin content)		
	Long tons	Value	Long tons	Value	
1938	49,699	$44,860,324	(2)	$298	205
1939	70,102	70,590,764	500	418,004	2,105

1940 [1]	16,615	3,536	4,590	6,091	137	383,328
1941 [1]	22,600	180	4,952	8,321	109	354,940
1942 [1]	24,082		1,333	3,230	154	594,095

[1] In addition, 15,153 long tons of terneplate clippings and scrap valued at $474,374 were exported in 1940, 751 long tons valued at $43,545 in 1941, and 76 long tons valued at $4,350 in 1942; not separately classified before January 1, 1940.

Foreign trade in miscellaneous tin manufactures and tin compounds, 1938–42

Year	Miscellaneous tin manufactures		Tin compounds (pounds)	
	Imports [1]	Exports [2]	Imports	Exports
1938	$19,453	$2,064,515	865	172,467
1939	20,106	1,098,140	5	204,362
1940	12,429	706,425	271	131,019
1941	2,266	1,456,353	7,224	137,424
1942	[3] 949	591,937		117,191

[1] Includes tin manufactures, n. s. p. f., tinfoil, tin powder, flitters, and metallics.
[2] Includes tin dross and tin-bearing scrap material other than tin-plate scrap.
[3] In addition, 505,346 pounds of tin dross, skimmings, and residues valued at $63,978 were imported; not separately classified prior to January 1, 1942.

Of special interest was the change in destination of exports. Australia and New Zealand were sent 27 percent, a striking example of Lend-Lease. Canada took 11 percent and Iran 5 percent, a large part of which was terneplate. The surprising volume of 50,000 tons for the U. S. S. R., taken in conjunction with the reported British shipments of 26,000 tons of tin for about 18 months after the German attack in June 1941 and the large volumes delivered from European

Digitized by Google

smelters in 1937–38, seem to indicate that Russia's wartime requirements exceed estimates of peacetime needs—contrary to experience in Canada, Great Britain, and the United States—and further suggest that its domestic production has not been as great as believed.[8]

Tin plate, terneplate (including long ternes), and taggers tin exported from the United States, 1941–42, by principal countries

PRICES

Notwithstanding the actual spread of war to the four quarters of the globe and retention of only a third of the world production centers by the Allies, the control of tin-selling prices has been most effective. Immediately before the outbreak of the 1914–18 conflict, Grade A tin sold at 31.75 cents a pound, New York. When the United States entered that war in April 1917 the price had risen to 55.91 cents, and for a year before that date averaged 43.89 cents. In 1918 a maximum of $1.10 was reached, and the year's average stood at 86.80 cents. In August 1939, or just before the invasion of Poland, the average price was 48.76 cents, then rose sharply in September but receded to the October average of 55.25 cents, an average not reached in the following 21 months. For the year August 1940–July 1941, the average was 51.45 cents. Effective August 16, 1941, the price of Straits tin was fixed at 52 cents a pound, New York, and has remained stationary at that level. Domestic Longhorn 3 Star tin has commanded the same

[8] See Minerals Yearbook, 1940, pp. 700–701, and Minerals Yearbook, Review of 1940, p. 688.

Digitized by Google

price since it became available in April 1942. The 2 Star grade has been priced at 51.125 cents.

Dealings on the London Metal Exchange were suspended on December 9, 1941, under Control of Tin Order 3, which also established a basic price of £275 for 99 percent minimum tin (or £278.10 for 99.9 minimum), delivered consumers' works.

World prices became nonexistent when maximum prices were established in the major consuming countries and trading ceased on the world's principal tin markets, although small sales at exceptionally high prices have been reported from some countries.

STOCKS

The total year-end tin content of all stocks in the United States was only 1½ percent below that at the end of 1941, but owing to the great curtailment in consumption they were equivalent to more than 3 years' supply without future increments at the indicated rate of use in the last half year. The make-up, as a result of Government control of acquisition and distribution, was materially altered. Industry pig-tin stocks were depleted to approximately half those on hand at the beginning of the year, whereas those in Government hands increased 28 percent; and ore supply (tin content), after increasing rapidly in the first 6 months, showed a slight loss in the second half but ended the year at 37,210 long tons or 55 percent higher than at the beginning.

Consumer surveys continued by the Bureau of Mines throughout 1942 showed year-end industry primary tin stocks at plants to be 32,100 tons, of which 20,600 tons were at tin-plate mills. Tin in transit ceased to be important in the supply situation and was 78 tons at the end of December. Secondary pig tin moved rapidly to consumers whose year-end stocks were estimated to be about 300 tons.

Data on world stocks have not been published since June 1941. Since control of tin supplies by governments is effective throughout the world and their distribution is earmarked, it may be said that visible stocks, as usually defined, no longer exist, although actual metal held in what has taken the place of private warehouses is probably more than double the visible stock averages of 1939–40.

Stocks of virgin pig tin in the United States, December 31, 1938–42, in long tons

	1938	1939	1940	1941	1942
Location of stocks:					
Afloat to United States [1]	4,150	12,663	22,627	[2] 15,000	[2] 900

WORLD ASPECTS OF TIN INDUSTRY

WORLD MINE PRODUCTION

Official statistics from all tin-producing countries have not been available since 1939, but it appears probable that production in 1942 was not much more than half that of 1941. Production in countries accessible to the Allies was somewhat below expectations, especially in Bolivia, where a decline of about 9 percent from the 1941 output was reported. In the East, notwithstanding Japanese assertions, output from Burma, British Malaya, and Netherlands Indies was probably only a small fraction of normal. In Thailand, too, there was some interference with mining, as well as plant damage, and China's inaccessibility doubtless held production low.

WORLD SMELTER PRODUCTION

Production from the world's smelters is likewise unknown, but it suffered severely when the British and Hollanders were forced from their Asiatic holdings. The Penang smelter, however, is believed to have continued in operation. Chinese inland smelter production doubtless did not exceed 7,000 or 8,000 tons; Japanese plants probably were operated at capacity. A small electric smelter was in operation in British Columbia. In less than 9 months, the Texas City smelter produced 15,696 long tons of tin; however, at the end of the year the annual production rate had risen to over 28,000 tons.

INTERNATIONAL TIN-CONTROL SCHEME

The third International Tin-Control Scheme expired December 31, 1941. A fourth was recommended for adoption in December 1941, but the outbreak of war in the Pacific and objections to proposed quotas by some of the participants delayed acceptance until September 9, 1942 (retroactive to January 1, 1942), when the agreement was formally ratified by representatives of the countries participating in the preceding Scheme, except Thailand and French Indochina.[9] The standard tonnages in the accepted form were those contained in the proposed text, except for the omission of Thailand. They vary considerably from the earlier bases, as actual experience with virtually unlimited production (130 percent of standard tonnage) for a year from July 1940 showed that some of the signatories could not attain the high quotas provided. Pending acceptance of the fourth agreement, tentative quotas had been set at 105 percent of the revised standard tonnages and were retained as far as known through 1942. The new agreement is to run for at least 5 years; the United States will have two representatives (nonvoting), one selected by the Government and the other a consumer representative, and there will be an additional representative for consuming countries other than the United States. Under the present war conditions the control agreement is purely nominal, but it does provide a continuing possibility of exercising some production control in the event of future wide fluctuation in demand.

In June 1938 a Buffer Pool was established, with the aim of stabilizing the price between £200 and £230. A stock of 15,512 tons was created between August 1, 1938, and July 1939; total purchases and sales were 66,428 long tons. In April 1942 it was decided to liquidate the remaining stock and complete the distribution of credit balances. The first distribution, in which all seven of the signatories to the Third Control Scheme participated, was made between November 1939 and February 1940 and amounted to £1,010,000. The final distribution of June–July 1942 amounted to nearly £2,285,000. In addition, balances to Thailand (£216,300) and to Indochina (£37,000) could not be paid because of legal difficulties arising under the Trading with the Enemy Act. It has been suggested that these funds be redistributed to the other parties to the Pool. The average realization without interest and before London overhead expense was £226.16.5 and the average distribution to the end of 1942 was £229.9.9.[10]

WORLD CONSUMPTION

Owing to the lack of basic statistical data for the past 3 or more years, the table of apparent world consumption is omitted from this review. Assuming the usual relationship between domestic and world consumption, the last named probably was about 125,000 tons in 1942 and may be expected to fall below that in 1943.

[9] American Metal Market, vol. 49, No. 251, December 31, 1942, p. 5, gives the full text of the agreement.
[10] The full report of the Executive was printed in American Metal Market, vol. 50, No. 96, May 20, 1943, pp. 5–6.

REVIEW BY COUNTRIES

Argentina.—Operations at the Pirquetas mine and the Pircas Creek placer continued during 1942, but with a smaller output than in 1941. The Buenos Aires smelter, which had treated most of the ore, could not produce enough tin to satisfy demands because of the contraction in ore supply, and some tin was imported.

Australia.—Production in 1942 has been estimated at 3,000 tons. Before the war, consumption of tin in Australia (including New Zealand) averaged 2,000 tons annually, and with the production of 3,000 to 4,000 tons there had been an exportable surplus. However, war needs have been greater than available supplies, and it was necessary to acquire a small tonnage from the United States for use in New Zealand. In 1943 mine output is expected to reach 4,000 tons but may not be realized owing to labor shortage and delays in obtaining dredges and other mining equipment. Some aid has been furnished through Lend-Lease, which also made available funds for canning equipment to expand production to provide food for American troops in Australia and New Zealand.

Effective May 1, 1942, the price of tin was set at £A371 per long ton, an increase of £A51. To encourage production from low-grade sources, it has been proposed to establish a pool for developing low-grade deposits by allocating £A10 per ton. The increased price of tin brought about a rise in output by small producers in 1942, but the lack of labor and continued withdrawal of competent men nullified the efforts of larger companies to expand their yield.

Belgian Congo.—The United States imported 10,474 tons of pig tin from the Belgian Congo during 1942 (11,030 tons in 1941). A sizable tonnage of pig tin was lost at sea through enemy action. Some cassiterite containing about 1,670 tons of tin mined in 1942 was to have been shipped to England. Mine output for 1943 has been estimated at 21,530 tons of tin, although it may not be reached because of a developing water shortage. The entire 1943 output of pig tin and cassiterite will be shipped to the United States. The Belgian Minister of Colonies is reported to have stated that by 1945 the Belgian Congo would be able to produce 35,000 tons of metallic tin annually.[11]

Bolivia.—The tin content of concentrates exported from Bolivia declined 8 percent from the 42,199-ton level of 1941 to 38,293 long tons in 1942, or 22 percent below the permissible quota of 49,106 tons (105 percent of standard) allowed under the Control Scheme. The United States was the destination of 53 percent of the 1942 export, and the remainder went to Great Britain. Inability to approach the quota was attributable to labor unrest that culminated in serious disorders at the end of the year, to a decline in grade of ore—the Patino Enterprises reported 2.83 percent in 1941 and 2.55 percent in 1942—accompanied by lower mill recoveries, and to general shortages in labor, equipment, and supplies. In an attempt to halt the downward production trend and if possible reverse it, financial aid and the assistance of numerous specialists were furnished by the United States.

Digitized by Google

At the request of the Bolivian Government a labor commission that worked jointly with Bolivian officials made a study of working conditions, wages, and security of workers, especially among miners. The commission submitted its report with recommendations to the Bolivian Government in March 1943, but its contents had not been disclosed in this country when this review was written. American technologists began studies of mining and metallurgical practices with the object of expanding output, especially at the smaller mines, and of improving the ore-dressing methods that are said to make recoveries of only about 50 percent at the plants of small and medium producers and of 72 to 80 percent by the major groups. To improve economic conditions and stimulate strategic materials output, the Bolivian Development Corporation was set up December 29, 1942, as a cooperative undertaking of the Bolivian Government and the Export-Import Bank, the latter furnishing credits of $15,500,000 out of a total capital of $26,000,000.

British Malaya.—The Japanese conquest of the Malay Peninsula was completed by the fall of Singapore on February 15, 1942. In 1941 about 68 percent of the output of the mines in the Federated Malay States came from European-owned and about 30 percent from Chinese-owned mines. About one-half of the production was obtained by dredging, and the bulk of the remainder by pumping, with small amounts from hydraulicking, open-cuts, and underground workings. Late in December 1941 the Government ordered the mine operators to destroy their properties. Annual reports of the principal British-owned companies indicate that many of them had sunk their dredges, destroyed power plants, and flooded their open-cast workings, but there is some doubt that the damage inflicted could have been as great as contemplated because of the rapid movement of the Japanese forces.

Burma.—The plant of Mawchi Mines, Ltd., was immobilized, and the property at Pazaung on the Salween River was evacuated under military orders on April 5, 1942. Lashio, the terminus of the Burma Road, was occupied by the Japanese April 29. The important tin mine area in lower Burma, south of Moulmein in the Tavoy and Mergui districts, was also gained by the Japanese.

Canada.—Although occurrences of tin have been reported from numerous localities in Canada, none has commercial importance. At present, however, Grade A tin is being produced at the Sullivan mine of the Consolidated Mining & Smelting Co. of Canada, Ltd., near Trail, British Columbia. At that mine cassiterite was discovered in the tailings from the lead-zinc concentrator in 1925, but as the amount of tin was small it was then considered only of academic interest. Subsequent and extensive research lead to the development of a satisfactory recovery process that is described in Canadian Institute of Mining and Metallurgy Bulletin 356, December 1941 (pp. 611–622). On March 1, 1941, a plant was put into operation, and in April 1942 an electric smelter that produced 560 tons of pig tin in 1942.

The discovery of a high-grade ore body carrying cassiterite and stannite in the Woolsey mine in the Revelstoke district, British Columbia, was reported.

In Manitoba the occurrence of tin has been known for many years. Great interest was aroused in the Rush Lake-Bird River district,

Digitized by Google

where a sample taken in 1940 had shown 0.3 percent tin. The Canadian Department of Mines and Resources examined what was believed to be the best cassiterite showing and recently issued a report.[12] Reviewing the current and earlier field work the writer concluded that "There is no known tin occurrence of commercial dimensions in Manitoba that contains sufficient tin to justify its recovery even under the stress of wartime requirements."

China.—Authentic statistical data on tin have been available only irregularly in recent years, but various estimates indicate that Chinese production rose from about 9,000 metric tons in 1935 to approximately 13,000 tons in 1940. The virtual isolation of southwestern China, serious inflation, the migration of workers to agricultural employment inducing a labor shortage, high wage levels, extremely high fuel and transportation costs, and inability to bring in supplies and equipment severely retarded development and production so that output in Yunnan fell to about 5,000 tons and that of China to roughly 7,000 tons in 1941, according to official figures.[13] The final closing of the Burma Road and some fighting along the Yunnan borders would have tended to hold down production in 1942, but the National Resources Commission has just reported that in Yunnan there was in 1942 a gain of about 1,000 tons over 1941;[14] total Chinese production may therefore have exceeded 7,000 tons. Although tin has not been mentioned specifically, it is believed a small tonnage was exported to Russia over the Northwest Highway in 1942, and a small amount has been flown out to India. Immediately after the attack on Pearl Harbor redoubled attempts were made to expedite the movement of tin over the Burma Road, and although a substantial amount did get through to the United States the unexpectedly early fall of Rangoon and evacuation of Burma resulted in the loss of large quantities of metal.

Germany.—Early in 1941 some authorities believed that Germany faced an immediate and dire tin shortage, a shortage more serious than in petroleum and food.[15] It is not yet, however, evident that a lack of tin has caused any pronounced decline in its war effort, because Germany has been and is waging a major war with very little supply. The German reserve position was probably better and the amount of loot greater than assumed. Civilian use of scarce materials had long since been reduced to negligible volume, and the use of substitutes even in essential industries had been strictly enforced. Intensive salvage campaigns had brought out much metal. At the same time, some new supply apparently reached Germany. Although the sinkings of several tin-carrying ships have been announced, it has been reported that since the fall of 1942 at least 26 vessels have run the blockade from Kobe to Bordeaux.

It has been claimed that great progress has been made in the substitution of bonderized lacquered plate for tin plate.[16] During the First World War considerable experience had been gained, presumably for general line cans, and much experimentation followed to determine the best basic coating, type of lacquer, and kind of plate to be used.

Digitized by Google

It was also determined that bonderizing and lacquering should be carried out by the can maker rather than by the rolling mill to avoid damage to surface in transport and handling. Body seams of this type of can cannot be soldered, and recourse was had to welding, for which an automatic welder was developed. This system is said to save incidentally 330 pounds of steel per 100,000 cans because of a smaller overlap.

A commercial-scale plant was erected in 1938. Bonderizing and lacquering were carried out in separate plants, but subsequently both were combined into a single unit. The article describes one operating plant that has a capacity of 5,000 to 6,000 cans an hour. Other plants appear to be operating.

The bonderized-lacquered cans are said to be satisfactory for meats and vegetable packs and for some but not all fruits. Future development is a questlon of lacquers with further possibilities if a scheme of full welding, including the ends, can be devised.

Italy.—The output of tin in Italy was about 300 tons in 1942. The only productive tin mines are near Villacidro, Cagliari, Sardinia, where a concentrating mill of 50 tons daily capacity is said to be producing 1 ton of high-grade concentrate a day.

Japan.—The Japanese policy of enslaving subject peoples has been extended to cover mineral and other wealth as well. In December 1942 Premier Tojo declared that Japan must win each decisive battle and make every effort to retain control of all natural resources gained in the initial victories. Such avowal of a determined policy of exploitation of subjugated territories was confirmed by the repeated reports, mostly originating from Japanese sources, that many tin mines and some smelters were again in full operation. Nevertheless, it appears improbable that ore production would have greatly exceeded smelter capacity, which when last reported was about 5,000 tons in Japan. So far as is known, Indochina's small reduction works were not harmed, reports of the destruction of the Penang smelter were conflicting, and the Hong Kong smelters were probably in large measure available. Japan had then access to ample smelting facilities to meet its apparent requirements of about 12,000 tons annually. The extremely rapid rise in pre-war apparent consumption points toward a large wartime accumulation; and if, as reported, high-grade concentrates are flowing to Japan from Malaya and the Netherlands Indies, its internal smelting capacity would be enlarged without addition to plant. Thus the Japanese Empire has not only obtained self-sufficiency in tin but may be establishing a long-term reserve against any eventualities, and any excessive accumulation would present an economic threat to post-war tin-market stability.

Some tin, probably several thousand tons, was shipped to Germany and Italy during 1942 as the British have disclosed the interception, sinking, or scuttling of ships carrying tin cargoes.

Mexico.—Mine production of tin in Mexico was 365 long tons in 1942 compared with 212 tons in 1941. Most of the 1942 production was utilized within Mexico, as 93 long tons were exported (108 in 1941). The price of tin was extremely high, being quoted at about $1.25 (U. S. currency) per pound. This led to the relatively marked increase in production and a drop in exports.

A new smelter designed for Metalurgica de Mexico, S. A., to treat tin, mercury, and antimony ores was completed in May 1942 at Tlalnepantla near Mexico City.

Digitized by Google

Netherlands East Indies.—Authentic information is lacking on the quantity of tin produced in the Netherlands Indies during the early part of 1942 before they fell into Japanese hands. However, 3,922 tons of pig tin and 7,977 tons of ore (tin content) reached the United States from that source during 1942. It has not been reported what portion of this was derived from stocks. The Japanese announced in the latter part of 1942 that the tin mines at Banka, Singkep, and Billiton had resumed operations, but it is doubtful that any great volume has been produced.

Nigeria.—Nigeria failed to meet expectations in 1942, as mine output was only 12,500 tons of tin or 7 percent below the permissible quota of 16,135 tons under the new Tin-Control Scheme. This was a particularly disappointing result, as the producers had been requested by the Government to increase output to the limit, and several companies reported that they were "picking the eyes out" of their deposits, regardless of the future. In some quarters the falling off in production was attributed to the Government restriction on prospecting, which has not yet been lifted.

Production, including stocks on hand and in transit, was taken over by the Ministry of Supply, December 9, 1941, but freight and insurance remained for account of the seller until July 1942. After long negotiations, the price to be paid Nigerian producers has been tentatively established. It is based upon costs and profits for the year ended August 31, 1939, or the average of the 3 years ended on that date, with adjustments for increases or decreases from those of the base period. Freight, marine, and war-risk insurance will no longer be paid by the sellers. It is understood that the new basis is £217 per ton (the 3-year average price for the period ended August 31, 1939) and that £150 per ton will be paid at port of shipment, with final settlement after assay in England.

Wages paid native workers have been increased as a result of Government intervention. Compulsory labor regulations have been introduced. It was said that more than 14,000 laborers are now working under these regulations and that the total force exceeds 70,000. Production plans call for an annual output of 20,000 tons if labor can be found.

Portugal.—Portuguese smelters have flourished in a small way owing to wartime conditions, as ore formerly exported is now treated within the country. A Metal Control Commission has been set up to control production and distribution and to fix prices. All tin must be offered to the Commission at a fixed price. Of the tin purchased, 25 percent is to be reserved for use in Portugal and the remainder is to be distributed between Axis and United Nations purchasers. Germany was offering very high prices for Portuguese tin early in 1942.

Spain.—Although it has been believed that Spain has sold tin to Germany the volume appears to have been small owing to the generally short supply. According to the Metal Bulletin of February 12, 1943, Spain had to import about 90 percent of its needs or 1,000 to 1,500 tons a year.

Union of South Africa.—The Zaaiplaats Tin Mining Co., Ltd., treated 42,690 tons of ore and recovered 182 long tons of concentrates in the year ended July 31, 1942, compared to 194 in the previous year. From its own and custom ores, the smelter produced more than 268 tons of pig tin in 1942 (143 tons in 1941). A third furnace has been added to the plant.

Digitized by Google

South-West Africa.—In the fall of 1942, discovery of a promising tin prospect at Kaokoveld, South-West Africa, was announced. The district lies in the northeastern part of the mandated territory near the Bechuanaland Protectorate border and is southwest of Caprivi Zipfel.

United Kingdom.—The consumption of primary tin in the United Kingdom has been brought down to around 14,000 tons annually compared with 30,000 tons in 1941 and 29,225 tons in 1940. Rigid control, under strict Government allocation, is exercised, and new measures for economizing in tin consumption are constantly coming forward. The tin-plate industry normally consumes about 40 percent of the tin used in the United Kingdom. The Welsh tin-plate industry operated at a very low level; permits to purchase tin plate were small, and most of the orders were for plate for lacquering. The electrolytic tin-plate process has been under investigation, but reaction appears unfavorable to the use of the thinly coated plate. Nevertheless, at the year end a small electrolytic unit was nearing completion.

Imports of ore from Bolivia and Nigeria apparently were lower in 1942 but were, however, adequate to meet smelter requirements. Trade journals generally believe that the tin position is comfortable in the United Kingdom.

U. S. S. R.—Russia has been almost wholly dependent on imports for its requirements, as its domestic production probably does not exceed 2,000 tons annually. It is believed that some tin was received from China during 1942; whether any was acquired from Japanese sources is unknown. Since June 1941 Great Britain has sent 26,000 tons of tin to Russia. It is unknown whether any was lost at sea from enemy action. According to The Metal Bulletin (London), "Japan might conceivably ship tin to Russia, who would be an equally ready buyer. At the moment, however, we have no information as to what trade, if any, is still going on between Russia and Japan."[17] It has been reported, however, that Japan is selling rubber and other products to Russia.

GENERAL STATEMENT

Domestic production of white arsenic in 1942 fell 12 percent below the 1941 record, but this decrease was more than balanced by a 59-percent increase in imports, permitting consumption to advance 5 percent. More than a third of the new supply of arsenic in the United States in 1942 came from Mexico. The quoted price of white arsenic remained at 4 cents a pound throughout 1942. Arsenic was placed under allocation control by the War Production Board May 22, 1942 (Order M–152).

[1] Apparent consumption.

DOMESTIC PRODUCTION

Production of white arsenic in the United States in 1942 declined 12 percent compared with 1941, chiefly because all stocked residues were consumed in 1941. The four producers were the American Smelting & Refining Co., Anaconda Copper Mining Co., Getchell Mine, Inc., and U. S. Smelting, Refining & Mining Co., which derived their output from bag-house and Cottrell dust and speiss. The Getchell company mines gold ores at Red House, Humboldt County, Nev.[1], and in 1942 began to recover the arsenic content by means of a Cottrell precipitator and accessory equipment. Of the domestic white arsenic production in 1942, 89 percent was crude (79–98 percent As_2O_3) and 11 percent was refined (99+ percent As_2O_3).

[1] Excludes crude consumed in making refined.
[2] Partly estimated.
[3] Includes production of 290 tons of white arsenic and sales of 279 tons contained in compounds made directly from arsenic-bearing ores.

The Anaconda Copper Mining Co. was the sole domestic producer of metallic arsenic in 1942. The Rare Metal Products Co., Belleville, N. J., manufactures arsenic sulfides.

FOREIGN TRADE [2]

Imports of white arsenic—principally from Mexico—increased 59 percent in 1942 compared with 1941. Exports of white arsenic, calcium arsenate, and lead arsenate declined materially.

White arsenic imported for consumption in the United States, 1938–42, by countries

Country	1938		1939		1940		1941		1942

Arsenicals imported into and exported from the United States, 1938–42, by classes, in pounds

Class	1938	1939	1940	1941	1942
Imports for consumption:					
White arsenic	28,475,783	29,347,810	19,857,310	20,583,253	32,700,351
Metallic arsenic	16,868	39,197	13,228	2,240	6,854
Sulfide	241,602	656,498	220,445	11,025	----------
Arsenic acid (H_3AsO_4)	55	210	----------	----------	----------
Calcium arsenate	400,000	1,627,193	432,785	1,230,960	215
Lead arsenate	----------	11,557	----------	----------	----------
Sheep dip	168,932	306,900	341,556	264,350	272,540
Paris green and london purple	103,556	45,823	25,603	12,000	----------
Sodium arsenate	11,881	7,482	----------	----------	----------
Exports:					
White arsenic [1]	4,534,000	6,356,933	3,278,558	[2] 3,231,536	610,206
Calcium arsenate	5,242,882	6,731,103	4,879,391	5,897,598	3,941,722
Lead arsenate	1,021,345	1,712,583	2,900,250	9,594,483	592,029
Paris green (cupric acetoarsenite)	[3]	[3]	[3]	[4] 224,976	171,464

[1] As reported to Bureau of Mines by the producers.
[2] Dealers exported an additional 1,077,244 pounds.
[3] Not separately classified.
[4] Figures cover July to December; not separately classified before July 1.

CONSUMPTION AND USES

Consumption of white arsenic in the United States in 1942, according to the War Production Board, is estimated at 42,411 short tons—73 percent in insecticides, 11 percent in weed killer, 4 percent each in glass and arsenic trichloride, 3 percent in dyes, 2 percent in wood preservative, 0.7 percent in gas purification, 0.4 percent in metallurgy, and 0.3 percent in pharmaceuticals. The results of a special consumer survey for 1941, conducted by the Bureau of Mines, are shown in the following table.

White arsenic consumed in the United States in 1941, by uses

Consumed in—	White arsenic consumed		Arsenicals manufactured (short tons)
	Short tons	Percent of total	
Insecticides:			
Lead arsenate (normal)	11,231	27.8	36,656
Calcium arsenate	11,192	27.7	29,684
Paris green	1,523	3.8	2,073
London purple	255	.6	673
Other insecticides [1]	479	1.2	[2]
Weed killer: Sodium arsenite	7,123	17.6	[3] 14,074
Poison bait: Sodium arsenite	414	1.0	781
Glass	4,281	10.6	----------
Wood preservative and wall board	1,366	3.4	----------
Dyestuffs	417	1.0	----------
Metal and alloys	246	.6	----------
Miscellaneous [4]	1,915	4.7	----------
Total white arsenic consumed	40,442	100.0	----------

[1] Includes zinc arsenate, basic lead arsenate, copper arsenate, etc.; figures not available for quantity manufactured.
[2] Partly estimated.
[3] Includes cattle dip, gas purification, arsenic trichloride, pharmaceuticals, paint, etc.

Calcium arsenate is the principal insecticide used to combat the boll-weevil, leaf-worm, and boll-worm infestations in the Cotton Belt; and lead arsenate is employed largely as a spray for apple and pear trees to exterminate codling and gypsy moths and for treating soil in the East to destroy Japanese-beetle grubs. The Department of

Digitized by Google

Agriculture anticipates an output of 45,000 tons of calcium arsenate, 31,000 tons of lead arsenate, and 1,250 tons of paris green in 1943. The 1943 outlook was summarized by W. H. Moyer, Insecticides and Fungicides Unit, War Production Board, as follows:

While it has been necessary to curtail sharply many normal uses of arsenic and to require substitution of less scarce materials in many directions, the basic requirements of agriculture for arsenical insecticides should be well provided for during 1943. In some cases, however, farmers will be urged to make greater use of items such as nicotine sulfate and cryolite, which are more plentiful than arsenicals.

Arsenic is an important reagent in glass manufacture, but antimony and cerium [3] are possible substitutes should such use become restricted. The effects of arsenic in glass, described in a recent paper,[4] are summarized as follows:

(1) *Blocking agent:* Chunks of arsenious oxide thrown into the glass pot sink to the bottom and rapidly volatilize with consequent beneficial stirring action. (2) *Fining agent:* Arsenic takes oxygen from niter and later liberates it as bubbles which sweep out carbon dioxide, steam, and other gaseous impurities. (3) *Oxidizing agent:* The oxidizing effect of arsenic helps keep the melt colorless by inhibiting the reduction of ferric oxide to green ferrous oxide. (4) *Reducing agent:* Arsenic is a reducing agent in respect to manganese and chromium, thus serving to tone down intense manganese colors and to improve chrome greens by removing the yellowish cast of chromates. (5) *Color stabilizer:* Since both the trioxide and pentoxide are colorless, arsenic is an excellent buffer to absorb variations in oxidizing-reducing conditions and thereby protect changes in the shade of sensitive colors. (6) *Opacifying agent:* The use of arsenic in making opal (milky-white) glass was widespread in the early days of the industry but is now limited primarily to the white calibration stripes on thermometers and laboratory glassware.

There are a number of disadvantages of using arsenic in glass: (*a*) Arsenic presents a health hazard to workers. This might be minimized by utilizing calcium or lead arsenate instead of arsenious oxide. (*b*) Excess additions cause cloudiness, as indicated by its use in opacification. (*c*) Arsenic is believed to attack glasshouse refractories, but this subject is controversial. (*d*) Arsenic cannot be used with cerium or neodymium decolorizers because glasses containing such combinations turn brown on exposure to sunlight. (*e*) Tubing and other glass that is reworked must not contain arsenic, because reheating is apt to precipitate gray or brown spots of metallic arsenic.

Sodium arsenite is used as a weed killer and as the lethal constituent of poison bait for fighting grasshoppers, Mormon crickets, and white-fringed beetles. Arsenic trichloride is used in the manufacture of lewisite poison gas and arsenic acid for khaki dyes. Arsenic wood-preservative paste and arsenic in other forms are employed to preserve telephone poles, fence posts, cane-fiber insulating board, railroad ties, and mine timbers. White arsenic is utilized in the Thylox method of purifying producer gas. White arsenic and metallic arsenic, its derivative, have limited application in the manufacture of antimonial lead and lead anodes and as a flux or alloying element in copper, brass, white bearing metal, and other alloys. According to the Public Health Service, manufacturers and distributors of arsenical drugs (chiefly the arsphenamines) sold 33 million doses in 1942 for the treatment of syphilis, compared with 18 million in 1941 and 13 million in 1940.

STOCKS

Producers' year-end stocks of white arsenic totaled 2,187 short tons in 1942 compared with 4,518 tons in 1941 and 6,944 tons in 1940. The 1942 figure excludes several thousand tons of 79-percent material held by Getchell Mine, Inc. The objective of the Government white arsenic stock pile to be accumulated by the Metals Reserve Co. was set in June 1942 at 6,000 short tons to be delivered by January 1943; this was augmented in July 1942 to provide for an additional 30,000 tons from Peru in 1943–44. The Government stock pile received its first shipment of white arsenic in October 1942 and by the end of the year had on hand 2,693 short tons—1,900 tons from Mexico and 793 tons from domestic sources. Producers' stocks of calcium arsenate and lead arsenate September 30, 1942, totaled 3,030 and 1,679 short tons, respectively, according to the Agricultural Insecticide & Fungicide Association.

PRICES

The average value of producers' sales of white arsenic was 2.1 cents a pound for crude and 2.7 cents a pound for refined arsenic in 1942 compared with 1.5 and 2.2 cents, respectively, in 1941.

Quotations on arsenic compounds at the end of 1942, according to Oil, Paint and Drug Reporter, were as follows (cents per pound for carlots at Eastern points): White arsenic, 4 cents; calcium arsenate, 7–8 cents; lead arsenate, 11–12 cents; sodium arsenite, 6¾–7¾ cents; sodium arsenate, 8 cents; paris green, 24 cents; and arsenic trisulfide (less than carlots), 30–35 cents. As compared with prices listed at the beginning of the year, these quotations represent a ½-cent increase for calcium arsenate and a 1- to 2-cent advance for lead arsenate; otherwise, they are unchanged. A quotation on arsenic metal has not appeared since 1940, when it was nominally 75 cents a pound.

Ceiling prices were placed on arsenic compounds by the Office of Price Administration in the first few months of 1943. The base price of lead arsenate in carlots was set at 11–11½ cents a pound February 8 (Maximum Price Regulation 315). An amendment effective April 6 fixed the base ceiling price of other insecticides as follows (cents per pound in carlots): Calcium arsenate, 7–7½ cents; paris green, 20–25 cents; london purple, 7–8 cents; magnesium arsenate, 15.3–18 cents; zinc arsenate, 10–11 cents; and zinc arsenite, 11¾–13¾ cents.

WORLD ASPECTS

World production of white arsenic in recent years, insofar as data are available, is shown in the accompanying table.

[1] Arsenic is also believed to be produced in Czechoslovakia, Iran, Peru, Turkey, and U. S. S. R. Production figures are not available for these countries.
[2] Data not available; in 1936 to 1940, inclusive, estimate included in total.
[3] Estimated.
[4] August to December, inclusive.
[5] Arsenic content of ores mined was as follows—1936: 23,312 tons; 1937: 20,954 tons; 1938: 21,480 tons; data not available for later years.

Australia.—More than 90 percent of Australia's output of white arsenic in 1942 was produced by the A. V. Leggo Co., Wiluna, Western Australia, from gold ores of the Wiluna and Moonlight mines. This source is being exhausted, but about 500 tons of white arsenic could be recovered annually from roaster fumes at the Comet mine, Marble Bar, Western Australia.

Canada.—Production of arsenic in Canada in 1942 was several times that in 1941. White arsenic is produced by Beattie Gold Mines, Ltd., Duparquet, Quebec; O'Brien Gold Mines, Ltd., Cadillac Township, Quebec; and Deloro Smelting & Refining Co., Ltd., Deloro, Ontario. The Deloro company has a contract with the United Kingdom to supply refined white arsenic at 7¾ cents a pound for the first 2,000 tons and 6¾ cents for additional quantities.[6] Wampum Gold Mines, Ltd., a company controlling the property of Douglas Lake Mines, Ltd., in Saskatchewan about 3 miles southwest of the Flin Flon mine, is developing an arsenopyrite body containing more than 10,000 tons of ore averaging 22 percent As and 0.5 ounce of gold per ton and 40,000 tons of lower-grade ore. The company has a contract to deliver 2,500 short tons of white arsenic within 2 years to the Metals Reserve Co., United States Government stock-piling agency.[6] The possibility of recovering 350 tons of white arsenic monthly from the Hard Rock and MacLead-Cockshutt gold mines in the Little Long Lac district of Ontario was considered seriously in 1942,[7] but the proposition later was abandoned.[8] Three mines in British Columbia—Hedley Mascot Gold Mines, Ltd., Kelowna Exploration Co.,

Ltd., and Bralorne Mines, Ltd.—ship arsenic-bearing concentrates to the Tacoma (Wash.) smelter of the American Smelting & Refining Co. The Canadian Pacific Railway uses antimonial lead babbitt containing 0.75–1.25 percent As and thus conserves appreciable quantities of tin.[9]

Ecuador.—A deposit containing 5–10 percent realgar has been located at Macas, Province of Cotopaxi, Ecuador.

Mexico.—Both production and exports of white arsenic in 1942 increased 44 percent over 1941. Exports totaled 18,065 metric tons—18,040 tons to the United States and 25 tons to Argentina.

Peru.—During the first half of 1942 the Oroya smelter of the Cerro de Pasco Copper Corporation produced 76 metric tons of lead-antimony bars containing 1.9 percent As. The corporation has a contract with the Metals Reserve Co., United States Government stockpiling agency, to deliver 10,000 tons of refined white arsenic during 1943.

Sweden.—Arsenic is recovered from Boliden ores in such quantities as to make Sweden the world's largest producer. White arsenic now stored in concrete silos in that country is believed to exceed 300,000 tons. It is reported that Great Britain has obtained an agreement from Sweden not to ship any of this material to Germany during the present war.

United Kingdom.—Refined white arsenic in 20-ton lots was quoted at £40 per long ton and metallic arsenic at £375 per long ton at the end of 1942, according to Metal Bulletin.

BISMUTH

By Allan F. Matthews

SUMMARY OUTLINE

	Page		Page
General statement	763	Stocks	765
Production	763	Prices	765
Foreign trade	764	World aspects	765
Consumption and uses	764		

GENERAL STATEMENT

Bismuth production in the United States in 1942 increased one-fourth over 1941, and consumption doubled. As there were no imports of metal to bridge the gap, stocks declined. Allocation control was instituted by the War Production Board over metallic bismuth February 1, 1943 (Order M–276), and over bismuth chemicals April 1, 1943 (Order M–295). The tariff on metallic bismuth was reduced 50 percent July 29, 1942.

PRODUCTION

Bismuth metal production in the United States reached an all-time high in 1942 and exceeded by one-fourth the record set in 1941. The Bureau of Mines is not at liberty to publish data showing domestic production of bismuth. Three primary producers recover by-product bismuth principally from domestic and imported lead and copper ores and from Mexican bismuth-lead bullion bars. The American Smelting & Refining Co. produces bismuth-lead alloys at its Selby (Calif.), Perth Amboy (N. J.), and Monterrey (Mexico) plants for refinement at Omaha, Nebr. From Montana copper and Utah lead ores the Anaconda Copper Mining Co. at Tooele, Utah, produces bismuth-lead bullion, which is refined by its subsidiary, International Smelting & Refining Co., East Chicago, Ind. The United States Smelting, Refining & Mining Co. ships bismuth-lead bullion from Midvale, Utah, for refinement at East Chicago, Ind., by its subsidiary, the U. S. S. Lead Refinery, Inc. The principal importer-consumer is the Cerro de Pasco Copper Corporation, New York, which produces large quantities of bismuth in Peru.

As a conservation measure, the use of metallic magnesium in debismuthizing lead was prohibited by the War Production Board November 14, 1941 (Order M–2b). The situation was allayed somewhat in 1942 by the allocation of magnesium turnings and sawings for this purpose, and in June 1943 it appeared that pure magnesium metal would again be available for debismuthizing lead.

Digitized by Google

FOREIGN TRADE[1]

Imports.—There were no "imports for consumption" of metallic bismuth in 1942, but "general imports" totaled 222,684 pounds—all of which apparently was either in bonded warehouses at the end of the year or had been reexported. Except for 570 pounds from Canada in 1938, all entries of metallic bismuth in 1938–42 were from Peru. As a result of the Reciprocal Trade Agreement with Peru, effective July 29, 1942, the tariff duty on metallic bismuth imports from "most-favored nations" has been reduced to 3¾ percent ad valorem compared with the former level of 7½ percent set by the Smoot-Hawley Tariff Act of 1930.

Bismuth and "compounds, mixtures, and salts of bismuth" imported for consumption in the United States, 1938–42

Year	Bismuth		Compounds, mixtures, and salts of bismuth	
	Pounds	Value	Pounds	Value
1938	92,298	$74,583	2,004	$3,387
1939	182,832	154,339	297	649
1940	123,880	118,260	4	31
1941	223,477	223,463	41	744
1942			7	22

Exports.—Bismuth exports in 1942 and in the latter part of 1941 are shown in the accompanying table. Earlier data are not available.

Bismuth exported from the United States, 1941–42

Bismuth commodity	1941 (September-December)[1]		1942

[1] Figures for matte and for metal and alloys cover July to December, inclusive; earlier data not available.

CONSUMPTION AND USES

Consumption of bismuth in 1942 was double that of 1941 and quadruple that of 1940. Bismuth metal shipped by producers and importers is estimated to have comprised 45 percent for use in pharmaceuticals and other compounds; 31 percent in solders and bearings; 15 percent in spotting fixtures, die setting, anchoring machine-tool bushings, and tube bending; and 9 percent in miscellaneous applications. Corresponding estimates for these four categories in 1941 are

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

60, 10, 15, and 15 percent, respectively. The data for 1942 are adjusted to exclude a significant quantity of metal stocked for use in 1943 but shipped in 1942 with the intention of using it in solder for armor-piercing shells, a requirement eliminated by the decision to employ crimping as an alternative of soldering. The year 1942 was the first in which the metallurgical applications of bismuth were quantitatively more important than the pharmaceutical.

Bismuth compounds are used in treating indigestion, venereal diseases, and wounds; in controlling blue mold on tobacco; and as a constituent of cosmetic powders. Alloys of bismuth are important because of their low melting point and because their volume either expands or is unchanged upon solidification from melts. Bismuth is a constituent of certain tin-lead solders; a recent series designed to conserve tin contains 75 to 82.5 percent Pb, 10 to 20 percent Sn, 3 to 5 percent Bi, 1.5 to 2 percent Ag, and 0.5 to 1 percent Sb. Low-melting alloys of bismuth (43–55 percent) with lead, tin, and cadmium are used in spotting fixtures, die setting, anchoring machine-tool bushings, and tube bending. Similar alloys, some with melting points as low as 117° F., are used in sprinkler apparatus, fire-detector systems, and valve seats for high-pressure gas containers. Additions of 0.1 to 1.5 percent bismuth to stainless steel, copper, and aluminum alloys improve machinability.

STOCKS

Inventories of bismuth held in the United States by the three domestic producers and the principal importer-consumer dropped 51 percent in 1942. In part the trend represented transfers from producer to Government stocks; thus, the over-all change in inventories at this level was a 33-percent decline.

Government-owned Metals Reserve Co. began stock-piling bismuth in July 1942 and by the end of the year had on hand 352,701 pounds—all refined in the United States but including 211,660 pounds imported from Mexico in bismuth-lead bullion. The Government stock pile comprised 592,586 pounds in mid-May 1943. The recommended stock-pile objective for bismuth was set in May 1942 at 500,000 pounds, in October at 1,500,000 pounds, and in November at 2,000,000 pounds.

PRICES

Bismuth metal continued throughout 1942 to be quoted at $1.25 a pound, ton lots, according to E&MJ Metal and Mineral Markets. Prices of bismuth compounds (in fiber drums)—likewise unchanged—were listed by Oil, Paint and Drug Reporter as follows, per pound: Subnitrate, $1.20; subcarbonate, $1.50; subgallate, $1.40; subsalicylate, $2.50; subiodide, $4.13; and trioxide, $3.65. Despite the steady base price, the quotation on subnitrate, subcarbonate, and subgallate in small lots (5-pound bottles) declined 11 to 15 percent in 1942.

WORLD ASPECTS

World production of bismuth approximated 1,700,000 kilograms (3,700,000 pounds) in 1942 compared with 1,400,000 kilograms (3,000,000 pounds) in 1941. It appears that the United Nations control about 88 percent of the new supply. The principal producing countries are the United States, Peru, Canada, and Mexico.

[2] In ore.
[3] Data not available. Estimate included in total.
[4] Partly estimated. Excludes content of some bismuth-tungsten concentrates.
[5] Excludes bismuth content of tin concentrates exported.
[6] Preliminary figure.
[7] Production included in total; Bureau of Mines not at liberty to publish figure.

Mexico.—Impure bismuth bars containing lead and small quantities of gold and silver are recovered as a byproduct of lead by the American Smelting & Refining Co., Monterrey, Nuevo Leon, Mexico, and are exported to the company Omaha (Nebr.) plant for refining. The lead operations at Monterrey of Campañia Metalurgica de Peñoles, S. A., subsidiary of the American Metal Co., Ltd., yield an unrefined lead-bismuth alloy which is treated on toll basis by the American Smelting & Refining Co.

Peru.—In 1942 Peru exported 355,728 kilograms of refined bismuth bars, containing 325,737 kilograms of bismuth, and 38,744 kilograms of bismuth-lead bars, containing 20,244 kilograms of bismuth. Of these exports, 73 percent went to the United Kingdom, 26 percent to the United States, and 1 percent to Chile. Bismuth ores are mined in the Department of Junin, principally at the San Gregorio mine and secondarily at the Colquijirca mine, and are smelted at Oroya by the Cerro de Pasco Copper Corporation.

Spain.—Bismuth ore produced in Spain, all in the Province of Córdoba, had a content of 42 metric tons of bismuth in 1940 compared with 95 in 1935, 180 in 1934, and 77 in 1933; there was no production in 1936–39 as a consequence of civil war. Some of the ore is consumed domestically, and the resultant output of bismuth metal was 11 metric tons in 1940 compared with none in 1936–39, 44 in 1935, 46 in 1934, and 26 in 1933.

United Kingdom.—London bismuth quotations were unchanged throughout 1942, according to Metal Bulletin. Bismuth ore, 30 to 35 percent, was listed at £110 to £125 a long ton, high-grade metal at 6s. 3d. a pound, and matrix alloy at 4s. 1d. a pound. Bismuth compounds and preparations were placed under export license control November 16, 1942.[8]

SUMMARY

Spurred onward by the unprecedented demand for airplanes and incendiary bombs, magnesium in the short space of a year has increased greatly in importance among the nonferrous metals. Production in 1942 exceeded the combined output of the industry from its inception in 1915 through 1941. On the basis of military requirements, the War Production Board announced the second expansion program early in 1942, increasing annual capacity to 725,000,000 pounds; this goal was cut back to 610,000,000 pounds and finally to 586,000,000 pounds later in 1942. Production of primary magnesium in 1942 totaled 97,925,684 pounds—200 percent more than in 1941 (32,589,052 pounds) and 682 percent greater than in 1940 (12,521,726 pounds). Magnesium output, having reached an annual rate of 218,800,000 pounds in December 1942, is expected to total nearly 375,000,000 pounds during 1943.

Salient statistics of the magnesium industry in the United States, 1940–42

	1940	1941	1942
Production of primary magnesium ..... pounds	12,521,726	32,589,052	97,925,684
Quoted price per pound [1] ..... cents	27.0	22.5	22.5
Exports ..... pounds	1,718,444	[2] 3,098,424	[2] 8,090,449
World production (estimated) ..... short tons	49,500	85,500	154,400

[1] Lowest nominal price (New York) for primary metal ingot 99.8 percent pure, carlots.
[2] Magnesium metal in primary form.

Dow Chemical Co. and Dow Magnesium Corporation produced the largest proportion of the domestic output and began operating a third plant during 1942. The carbothermic reduction plant of Permanente Metals Corporation continued production throughout the year, and most of the technical difficulties appear to have been solved. Permanente began production from a new ferrosilicon plant at Manteca, Calif., during the year, and seven new companies in the field began operations in 1942, contributing substantially to the year's output. These included Diamond Magnesium Co. at Painesville, Ohio; Basic Magnesium, Inc., at Las Vegas, Nev.; Ford Motor Co.

Digitized by Google

at Dearborn, Mich.; International Minerals & Chemicals Corporation at Austin, Tex.; Magnesium Reduction Co. at Luckey, Ohio; Mathieson Alkali Works, Inc., at Lake Charles, La.; and New England Lime Co. at Canaan, Conn.

Domestic consumption of primary and secondary magnesium in 1942 totaled 84,525,700 pounds compared with 29,346,600 pounds in 1941. As in 1941, demand for the metal continued greater than the available supply, and magnesium topped the list of critical metals issued periodically by the War Production Board. The situation had eased somewhat by mid-1943, but virtually all the metal was still being allocated to direct military uses and to Lend-Lease account and will probably continue to be so allocated for the duration of the war. Of the primary magnesium shipped or used in 1942, approximately 58 percent went into the production of magnesium-base alloys, virtually all for structural products; 12 percent into other alloys, chiefly aluminum; 17 percent into magnesium products, chiefly nonstructural; 11 percent for export account; and 2 percent into other uses. No primary magnesium was imported, but more than 8,000,000 pounds were exported in 1942. The second major price reduction in less than 2 years was made when the Dow Chemical Co. reduced its price on 99.8-percent magnesium ingot, carlots, from 22.5 cents to 20.5 cents a pound on January 1, 1943. The Office of Price Administration ordered that, effective February 1, all ingot sales except those to Metals Reserve Co. would be regulated by a ceiling price of 20.5 cents a pound.

World magnesium output reached a new peak in 1942, and estimates based on meager statistical data indicate that Germany remained the largest producer. Axis and Axis-dominated nations produced an estimated 52 percent of the world output in 1942, but it is anticipated that the United Nations will greatly exceed Axis production in 1943.

PRODUCTION

Primary magnesium.—Domestic production of primary magnesium in 1942 totaled 97,925,684 pounds, a 200-percent advance over the 32,589,052-pound output of 1941. Primary magnesium shipped or used (sales) totaled 94,840,771 pounds, or 205 percent more than in 1941 (31,056,947). Although the Dow Chemical Co. and the Dow Magnesium Corporation produced most of the output, the Permanente Metals Corporation, New England Lime Co., Mathieson Alkali Works, Inc., Ford Motor Co., Basic Magnesium, Inc., Diamond Magnesium Co., Magnesium Reduction Co., and International Minerals & Chemicals Corporation contributed a substantial share.

United States production is expected to reach nearly 375,000,000 pounds in 1943 and 530,000,000 pounds in 1944. By June 1944 it is estimated that domestic facilities will be producing at their rated ultimate capacity of 586,000,000 pounds. In early 1941 peak estimates of military requirements amounted to only 72,000,000 pounds, but by June 1941 requirements had increased to an estimated 411,000,000 pounds, according to the Office of Production Management; of this total, 153,000,000 pounds was for so-called "contingency requirements." The first expansion, increasing capacity to 400,000,000 pounds annually, to take care of revised requirement schedules, was announced June 13, 1941.

Digitized by Google

At the end of 1941, military requirements had risen to the point where peak possible consumption was stated as 670,000,000 pounds, including 470,000,000 pounds for Chemical Warfare Service and for bombs to be exported (now estimated at only 170,000,000 pounds). In February 1942 the War Production Board announced its second expansion program designed to increase total annual primary metal capacity to 725,000,000 pounds. Requirements were again revised—this time downward to approximately 600,000,000 pounds—and the construction program was cut back to 610,000,000 pounds. The goal was again cut back to 586,000,000 pounds, and this capacity, plus about 32,000,000 pounds of secondary metal, is expected to supply enough magnesium for all requirements planned at present. About 90 percent of all the domestic magnesium-producing capacity will be Government-owned when the expansion programs are completed.

Dow Chemical Co., the largest domestic producer during 1942, produced metal from an underground brine containing 3.2 percent $MgCl_2$ at its 18,000,000-pound Midland (Mich.) plant and from sea water at its 36,000,000-pound Freeport (Tex.) plant. At Midland the bromine and the sodium and calcium salts are removed from the brine by evaporation, filtration, and fractional crystallization, and some chlorine is added during the process. The purified magnesium chloride solution remaining is concentrated further by crystallization to give $MgCl_2 \cdot 6H_2O$ (hexahydrate). The hexahydrate is dried to give a nearly anhydrous magnesium chloride ($MgCl_2 \cdot H_2O$) and, with some added sodium chloride, is then electrolyzed in the fused state in rectangular cast-steel cells. At Freeport, Tex.,[1] vast quantities of sea water containing only about 0.12 percent magnesium (0.48 percent $MgCl_2$) are treated with hydrated oystershell lime. Magnesium hydroxide is precipitated and then reacted with hydrochloric acid produced from gases given off by the electrolytic cells. The resulting solution is evaporated to give crystals of the hexahydrate, which are dried and treated as at Midland.

Dow Magnesium Corporation was formed to construct and operate two 72,000,000-pound magnesium plants at Velasco, Tex., and Marysville, Mich., both using the standard Dow process. The Velasco plant uses the same process as the Freeport (Tex.) plant of the Dow Chemical Co., and is only 7 miles away; it began producing magnesium from sea water in June 1942. On April 8, 1943, the mammoth Marysville plant began to produce magnesium.[2] Ultimately this plant will use magnesium chloride shipped from Ludington, Mich., where 10-percent magnesium chloride brines were tapped and developed in 1941. The Ludington feed plant was not completed and could not supply the Marysville reduction plant for the first 2 months of operation; during this period magnesium chloride was shipped from Texas in hopper-bottomed cement cars. Although the process used to convert magnesium chloride to metal at Marysville is essentially the same as at Midland, the new plant embodies many notable advances in chemical engineering. Because of the shortage of copper, silver bus bars carry electric current in the Marysville plant. The silver—2,000,000 pounds valued at $20,000,000—was loaned to the Defense Plant Corporation by the Government and will be returned when the bars can be replaced by copper.

The Mathieson Alkali Works, Inc., which, up to June 6, 1943, was producing only small amounts of metal from a pilot plant at Lake Charles, La., began production from the first unit of its 54,000,000-pound plant on that date. Mathieson has developed a special electrolytic cell jointly with the Consolidated Mining & Smelting Co. (Trail, B. C.) known as a Trail-Mathieson cell.[3] Advantages claimed for this cell over the standard Dow cell are that concentrated chlorine gas is produced instead of hydrochloric acid gas and that a lower consumption of electric current per pound of metal is indicated. The raw material used is dolomite, $Mg,Ca(CO_3)_2$, which is calcined and treated with waste calcium chloride liquor from the company Solvay process. Hot waste carbon dioxide gas from the calcining kilns is passed through the solution; calcium carbonate is precipitated and filtered off. The magnesium chloride brine is concentrated, evaporated to hexahydrate, and dried to a nearly anhydrous form for electrolysis.

Production began at the 36,000,000-pound plant operated by the Diamond Magnesium Co. at Painesville, Ohio, late in September 1942. Like Mathieson Alkali, Diamond treats dolomitic lime with the chloride waste liquors from its Solvay ammonia-soda process to produce magnesium hydroxide and calcium chloride. The slurry is carbonated by kiln gases, and calcium carbonate is precipitated. The remaining solution is concentrated and crystallized, and the crystals are dried to produce a nearly anhyrous magnesium chloride cell feed. In addition to the recovery of magnesium chloride by using waste chloride liquors, Diamond treats some calcined dolomite directly with hydrochloric acid from the cell gases. The regular Dow-type cell is used in electrolytic decomposition of the chloride.

Magnesium was produced by International Minerals & Chemicals Corporation at its 24,000,000-pound plant at Austin, Tex., starting in November 1942, from purchased magnesium chloride cell feed. Union Potash & Chemical Co. at Carlsbad, N. Mex., a subsidiary of International, began supplying the Austin plant with magnesium chloride cell feed derived as a byproduct from its potash operations in the early summer of 1943. Part of the cell feed for the Austin plant is being obtained from hydrated dolomite quarried in Burnet County, Tex., which is carbonated with kiln gases and treated with byproduct hydrochloric acid from the Dow-type electrolytic cells.

On August 31, 1942, Basic Magnesium, Inc., began production from its huge 112,000,000-pound plant at Las Vegas, Nev. The plant, which uses the M. E. L. process developed by I. G. Farbenindustrie, A. G., in Germany and later used by Magnesium Elektron, Ltd., at Clifton Junction, England, is the largest magnesium plant in the world and is patterned after the Magnesium Elektron (Ltd.) plant in England. Production was slow in getting under way, owing to concentrating difficulties at the magnesite mine in Gabbs Valley, Nev., and to other factors. During the summer and fall of 1942 charges of company mismanagement were made by Senator Bunker of Nevada and others, and in late October it was announced that the 52½-percent interest in the company owned by Basic Refractories, Inc., of Cleveland, Ohio, had been purchased by the Anaconda Copper Mining Co. for a reported $75,000. Production during April 1943 had risen to about 63 percent of rated capacity. Raw magnesite

and magnesium oxide sinter are ground and briquetted with coke and British Columbia peat moss. To produce a completely anhydrous magnesium chloride, the briquets are roasted and treated with chlorine gas obtained partly from the cells and partly from the electrolysis of sodium chloride. The principal difference between the electrolysis in the M. E. L. process and in the Dow process is that the latter uses a monohydrated magnesium chloride cell feed whereas the former uses a completely anhydrous feed.

Permanente Metals Corporation operated two plants using different processes during 1942. One plant which began operations late in 1941 uses the so-called Hansgirg process, a carbothermal reduction method, but was a great disappointment throughout most of 1942. Production lagged far behind schedule, and reports of accidents and explosions were numerous; however, in the latter part of 1942 and during the first half of 1943 production has increased markedly, and there are indications that most of the technical difficulties have been overcome. In the Hansgirg process, coke and caustic calcined magnesia are mixed and heated in a 3-phase 8,000-kv.-a. electric-arc furnace to about 2,100° C. The coke reduces the magnesia, and the magnesium becomes vaporized. Shock cooling by natural gas at 200° C. and collection of the dust by Cottrell precipitators yields a finely divided magnesium powder mixed with carbon, magnesia, and other impurities, which is collected as a doughy mixture in oil. The mixture is redistilled, and the magnesium is removed as high-purity crystals from the top of the distilling furnace. Sea-water magnesia for the process was obtained from the Westvaco Chlorine Products Co. until late in 1942, when Permanente began operating its own sea-water magnesia plant at Moss Landing, Calif. The other metal plant operated by Permanente is at Manteca, Calif., and uses the new ferrosilicon process developed by Dr. L. M. Pidgeon of Canada. Production at this plant began in August 1942.

Including the Permanente Metals Corporation plant at Manteca, six companies are operating plants using the ferrosilicon process.[4] The other five are: Ford Motor Co., Dearborn, Mich.; Electro Metallurgical Co., Spokane, Wash.; Magnesium Reduction Co. (National Lead Co.), Luckey, Ohio; Amco Magnesium Co. (American Metals Co.), Wingdale, N. Y.; and New England Lime Co., Canaan, Conn. Research on this process was pioneered by Dr. L. M. Pidgeon of the Canadian Research Council, the Ford Motor Co. at Dearborn, Mich., and the Electro Metallurgical Co. at Niagara Falls, N. Y. Dolomite, a double carbonate of calcium and magnesium occurring in virtually limitless quantities in the United States,[5] is the magnesium-bearing raw material used. Dead-burned dolomite and ferrosilicon (75-percent grade) are briquetted and charged into a horizontal or vertical nichrome-steel retort equipped with a condenser unit and heated at about 1,150° C. under a high vacuum. The magnesium oxide in the calcined dolomite is reduced by the ferrosilicon, and the metal is vaporized and collected at the cooled end of the retort. After most of the magnesium has been driven off the charge, the retort is opened, and a ring of high-purity magnesium crystals is

removed. The residue in the retort—largely dicalcium silicate, calcium oxide, and some magnesium oxide and ferrosilicon—is removed and disposed of, and the cycle is begun again with a fresh charge of briquets. Approximately 12 pounds of dolomite and 1 pound of ferrosilicon are required to produce 1 pound of magnesium metal. The process was adopted because it requires less electric power than the electrolytic processes, it employs dolomite (a cheap and abundant raw material), and the plants utilizing it require a minimum of time for construction.

The Ford Motor Co. plant, which began operations in May 1942, experienced trouble with collapse of its retorts owing to internal and external corrosion and the shock of heating. Research showed that if the retorts could be embedded in a bath of molten silicate glass, the possibility of collapse would be lessened and a mild low-carbon steel could be used. Original plans were changed to include 24 Toledo furnaces and 12 silicate furnaces at the Dearborn plant.

Vertical internally heated retorts are used at the Electro Metallurgical Co. plant at Spokane, Wash., which began operation on May 26, 1943. This company is building its own 48,000,000-pound ferrosilicon plant, which is already in partial operation at Spokane.

In September 1942 the plant of the New England Lime Co. at Canaan, Conn., began producing magnesium. After several months of operation, difficulties were experienced with the collapse of retorts; but the company's experiments showed that the life of these retorts could be prolonged by the simple expedient of blowing them up again with compressed air.

Magnesium Reduction Co. at Luckey, Ohio, began operations in December 1942, using high-grade Ohio dolomite, and Amco Magnesium Co., Wingdale, N. Y., began production in April 1943 using purchased lime. Local dolomite will be employed by Amco as soon as the calcining kilns are completed.

Explosions and fires destroyed the plants of Magnesium Products, Inc., Los Angeles, Calif. (aircraft castings), and National Magnesium Corporation, Newark, N. J., during 1942. In March 1943 the plant of the Pacific Coast Chemical Co. at Aberdeen, Wash., was destroyed by a series of explosions and a large fire.

Among old and new companies that expanded or began to fabricate magnesium in 1942 and the first half of 1943 through the Defense Plant Corporation were: American Radiator & Sanitary Corporation, Elyria, Ohio, and Louisville, Ky.—castings for aircraft engines and wheels (3,600,000 pounds at each plant annually); Chevrolet Motor Division, General Motors Corporation, Saginaw, Mich.—castings (4,800,000 pounds annually); Bendix Aviation Corporation, Bendix, N. J.—castings (1,920,000 pounds annually); Deere & Co., East Moline, Ill.—castings (2,400,000 pounds annually); Dow Chemical Co., Bay City, Mich.—sand castings (1,680,000 pounds annually), and Midland, Mich.—extrusions (2,640,000 pounds annually); Ebaloy Foundries, Inc., Rockford, Ill.—castings (1,800,000 pounds annually); Ferro Enamel Corporation, Bedford, Ohio—powder (200,000 pounds monthly); Hills-McCanna Co., Chicago, Ill.—sand castings (600,000 pounds annually); Howard Foundry Co., Chicago, Ill.—sand castings (6,000,000 pounds annually); Humphreys Mfg. Co., Mansfield, Ohio—castings (2,400,000 pounds annually); Marshall Stove Co., Lewisburg, Tenn.—castings (4,200,000 pounds annually); Maryland Sani-

tary Mfg. Co., Baltimore, Md.—castings (6,000,000 pounds annually); Michigan Light Alloys, Grand Rapids, Mich.—castings (4,200,000 pounds annually); Revere Copper & Brass, Inc., Baltimore, Md.—sheet (6,000,000 pounds annually), and Rome, N. Y.— forgings; Springfield Bronze & Aluminum Co., Springfield, Mass.—castings (3,600,000 pounds annually); U. S. Radiator Corporation, Geneva, N. Y.—castings (3,600,000 pounds annually); and Wellman Bronze & Aluminum Co., Cleveland, Ohio—castings (3,600,000 pounds annually).

Secondary magnesium.—Recovery of secondary magnesium totaled 6,238 short tons (including secondary magnesium incorporated in primary magnesium ingot) in 1942 and required the consumption of 7,317 tons of magnesium scrap, which was almost entirely new scrap. Of the quantity of magnesium recovered, 6,045 tons were as ingot, and 93 tons went into castings, 46 into aluminum alloys, 2 into lead alloys, 1 into zinc alloys, and 51 into chemical reagents. Additional information on secondary magnesium will be found in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION

Magnesium remained under strict priority control during 1942 to insure that virtually all of the metal was channeled into military uses for the production of airplanes and incendiary bombs. Apparent consumption totaled 86,750,322 pounds—an increase of 210 percent over 1941. Of the primary magnesium shipped or used in 1942 (94,840,771 pounds), approximately 58 percent was used in the production of magnesium-base alloys, virtually all for structural products; 12 percent in other alloys, chiefly aluminum; 17 percent in magnesium products, chiefly nonstructural; 11 percent for export account; and 2 percent in other uses.

Actual consumption of magnesium (from primary and secondary sources) totaled 84,525,700 pounds. Of this, 75 percent was used

Production, sales, exports, and apparent consumption of primary magnesium in the United States, 1940–42, in pounds

Year	Production	Sales	Exports	Apparent consumption [1]
1940	12,521,726	12,823,633	[2] 1,668,765	11,154,868
1941	32,589,052	31,056,947	3,098,424	27,958,523
1942	97,925,684	94,840,771	8,090,449	86,750,322

[1] Does not consider fluctuations in consumers' stocks and metal derived from scrap. Withdrawals from producers' stocks totaled 301,907 pounds in 1940; additions to producers' stocks totaled 1,447,615 pounds in 1941 and 3,084,913 in 1942.
[2] Of the 1,718,444 pounds of metal exported, 49,679 pounds consisted of magnesium alloy.

Actual domestic consumption of primary and secondary magnesium (magnesium content), 1941–42, by uses, in pounds

Use	1941	1942	Use	1941	1942

in the manufacture of magnesium-base alloy structural products, 17 percent in aluminum alloys, 7 percent in pyrotechnics, and 1 percent in other uses.

Magnesium-base alloy structural products manufactured and sold or used in the United States increased 233 percent over 1941. The manufacture of nonstructural products sold or used increased 658 percent. Of the structural products sold or used, sand castings comprised 70 percent, permanent mold castings 24 percent, die castings 3 percent, sheet 2 percent, and other structural products 1 percent. Of the nonstructural products, powder comprised 59 percent, stick 40 percent, and shavings, turnings, wire, ribbon, and other products 1 percent. The value of sand castings manufactured in 1942 averaged $2.22 a pound, permanent mold castings $0.83, die castings $1.87, and all castings $1.87 a pound (compared with $2.03 in 1941).

Magnesium products (other than ingot) manufactured in the United States and sold or used by the companies manufacturing the products, 1940–42

(including propellers), 23 percent for wheels, 7 percent for frames, and 4 percent for accessories. Sand, die, and permanent mold castings comprised 96 percent of all the magnesium-alloy structural products sold or used in aircraft.

Fabricators of magnesium structural products increased from 38 in 1941 to 59 in 1942 and of nonstructural products from 6 to 19. By the end of 1942, 32 companies were producing sand castings, 17 permanent mold castings, 11 die castings, 3 extruded products, 3 forgings, and 20 powder. The largest producers of alloy structural products were the American Magnesium Corporation, Dow Chemical Co., Bohn Aluminum & Brass Corporation, Doehler Die Casting Co., Wright Aeronautical Corporation, Eclipse Aviation Co. (subsidiary of Bendix Aviation Corporation), Ford Motor Co., Wellman Bronze & Aluminum Co., International Silver Co., Superior Bearing Bronze Co., Stewart Die Casting Division of Stewart Warner Corporation, Hills-McCanna Co., Magnesium Products Corporation, and Dalmo Victor Co. Producers of powder included American Magnesium Corporation, California Fuel & Utilities, Inc., Imperial Paper & Color Corporation, Magna Manufacturing Co., Metals, Inc., National Fireworks, Inc., National Magnesium Corporation, New England Magnesium Co., Pilgrim Ordnance Works, Reade Manufacturing Co., Universal Match Co., and U. S. Magnesium Corporation.

WAR MEASURES

The magnesium General Preference Order (M–2–b) now in force was originally issued on November 14, 1941, to conserve and direct the distribution of magnesium, and was to expire October 31, 1942. On October 31 the War Production Board announced that the order would continue in force until December 31, 1942. On December 31 the Director General for Operations announced a simplification of order M–2–b to bring it into line with the form of allocation orders then being issued. The amended order eliminates all references to preference ratings because the supply of magnesium and magnesium products is directly allocated to users. Provision was also made for stricter segregation of scrap in accordance with A. S. T. M. alloy designations to facilitate its handling and reprocessing.

PRICES

At the request of the Office of Price Administration, Dow Chemical Co. reduced its base price of standard four-notch magnesium ingot from 22.5 to 20.5 cents a pound on January 1, 1943. Effective February 1, the Office of Price Administration, in Maximum Price Regulation 314, established 20.5 cents as the maximum price per pound for standard four-notch ingot except for sales to the Metals Reserve Co. Magnesium-alloy ingot maximum prices included in the above regulation were: Incendiary bomb alloy, 23.4 cents; 50-50 magnesium-aluminum alloy, 23.75 cents; A. S. T. M. B80–41 T No. 11 and A. S. T. M. B94–41 T No. 13, 25 cents; and all other alloys, 23 cents. On February 1, 1943, in Revised Maximum Price Regulation 125, the price of magnesium castings was reduced 3 cents a pound. Magnesium scrap and remelt ingot were controlled under the General Maximum Price Regulation during 1942, but on January 20, 1943, specific prices for various types of scrap and various grades of ingot were established under Maximum Price Regulation 302.

FOREIGN TRADE[6]

Imports of magnesium in all forms during 1942 totaled 1,386 pounds valued at $856, of which 57 pounds were scrap from Canada; 902 pounds, alloys from the United Kingdom (magnesium content); 24 pounds, classed as sheets, tubing, ribbon, etc., from Canada; and 403 pounds, powder from Canada (257 pounds) and the United Kingdom (146 pounds). Exports of magnesium metal in primary form during 1942 aggregated 8,090,449 pounds valued at $1,945,164, of which 7,118,469 pounds went to the United Kingdom, 971,380 to Canada, and 600 to the Union of South Africa. Comparable exports in 1941 were 3,098,424 pounds valued at $860,486. Exports of magnesium metal in other forms during 1942 totaled 298,595 pounds valued at $99,517, of which 265,000 pounds were consigned to the United Kingdom, 33,559 to Canada, 35 to Argentina, and 1 to New Zealand. Magnesium powder exported during 1942 totaled 43,582 pounds valued at $66,038, of which 21,292 pounds were sent to Canada, 11,200 to Turkey, 6,380 to Australia, 2,005 to Cuba, 1,250 to China, 1,120 to New Zealand, 200 to Portugal, 72 to Iceland, and 63 to Argentina. Comparable export figures for magnesium powder and magnesium in other forms, excluding primary, are not available for 1941, as official records date only from July 1, 1941. Magnesium metal has been under export control since November 5, 1940.

TECHNOLOGIC DEVELOPMENTS

The outstanding development of 1942 was the introduction of the ferrosilicon process[7] for extracting magnesium metal from dolomite. The process was worked out by Dr. L. M. Pidgeon of the Canadian National Research Council in 1941, and refinements were added during 1942 by engineering departments of the various companies that began using the process in 1942 and 1943. This and other methods have been described herein under Production.[8] The Bureau of Mines continued to investigate the Doerner[9] process, whereby magnesium is produced directly by electrothermic reduction of the oxide with carbon and the magnesium vapor is shock-cooled and condensed by a light oil spray; research was also continued on the direct reduction of magnesium oxide in an electrolytic cell. At Pullman, Wash., the Bureau is also investigating the production of pure magnesium oxide from Washington magnesite and dolomite by the carbon dioxide leaching process.

Several extensive dolomite and magnesite deposits in the Boulder Dam area that may be used as additional sources of raw material for the Basic Magnesium (Inc.) plant at Las Vegas are described in a Bureau publication.[10] At Boulder City, Nev., work was done on several methods to extract pure magnesium oxide from high-grade Nevada dolomites, and a small-scale plant has been proposed by the

Bureau to be built and operated in cooperation with Basic Magnesium, Inc. Metallurgists at the Bureau's Norris (Tenn.) station are endeavoring to develop a low-cost process for extracting magnesium oxide from olivine, which occurs in large quantities in Georgia, North Carolina, and Washington.[11]

All-magnesium planes have been brought within the realm of possibility by the development, after 2 years of research by engineers of the Northrop Aircraft Co., Inc., of a new welding process by which magnesium can be arc-welded in an atmosphere of helium.[12] "Heliarc" welding has proved successful where other welding methods have failed in dealing with high-temperature melting and heat-resisting magnesium alloys. Concise metallographic techniques most desirable for routine examinations of macro- and micro-structures in magnesium alloys have been worked out,[13] and research work has led to increased knowledge of the treatment and properties of magnesium alloys.[14]

The rapidly growing demand for magnesium and magnesium-base alloys has led to a great deal of research on corrosion characteristics.[15] The early belief that magnesium and its alloys were much less resistant to corrosion than other alloys in engineering use has been abandoned in the light of more precise knowledge. If cutting tools are properly designed and maintained, magnesium alloys may be machined dry with safety, as shown by current British practice.[16] Recent research has shown that silver can be plated on magnesium, after cathodic cleaning and anodic treatment of the surface, in a boric acid cyanide electrolyte.[17]

Numerous patents relating to magnesium were granted during 1942, including the following: Thermal reduction of magnesium oxide with calcium carbide to produce magnesium metal and subsequent recovery from the residue and recycling of carbon and calcium carbonate (United States Patent 2,289,627); thermal reduction of magnesia in a calcined magnesia-containing ore with carbon, whereby metallic magnesium is liberated as a vapor and a molten residue is generated which exerts a washing action on the vapor and reduces the dust problem (United States Patent 2,286,209); a new method for producing magnesium-zirconium alloys in any desired shape—hitherto considered impossible (United States Patent 2,286,311); production of aluminum-clad magnesium by first coating an extruded slab of magnesium alloy with zinc (United States Patent 2,301,332).

WORLD PRODUCTION

World production of magnesium in 1942 reached an unprecedented high mark of more than 140,000 metric tons—81 percent more than the production in 1941. Although the statistical background for many

of the production figures is weak, it is estimated that about 52 percent of the output was under Axis control and 48 percent under control of the United Nations. Production in 1943 will greatly eclipse the 1942 total, and the United Nations will greatly improve their position with respect to Axis and Axis-dominated countries.

Estimated world production of magnesium, 1938–42, by countries, in metric tons

Country	1938	1939	1940	1941	1942
Australia				200	430
Canada					230
France	1,800	2,500	2,000	3,000	3,000

United States	2,918	3,039	5,680	14,782	44,418
Total	23,900	30,900	44,900	77,600	140,100

Australia.—The 1,000-ton magnesium plant owned by Broken Hill Proprietary Co., Ltd., at New Castle, New South Wales, began operations in July 1941 and produced at nearly 50 percent of rated capacity in 1942. Local magnesite is ground, calcined, and reduced under vacuum with ground calcium carbide to produce magnesium metal. Attention has recently been given to the possibility of producing magnesium from the extensive deposits of dolomite at Smithton, on the northwest coast of Tasmania. Magnesite deposits in the Dial Range are also being investigated as a possible source of the metal.

Canada.—Production began in early fall of 1942 in the new ferrosilicon-process plant of Dominion Magnesium Co., Ltd.,[18] at Haley's Station, near Renfrew, Ontario. The rated capacity, reportedly attained in February 1943, is 10 tons of magnesium a day. The retorts are charged with briquetted ferrosilicon and calcined dolomite and heated, after evacuation, by silicon carbide globars. After an 8-hour period the retorts are opened, the crystalline magnesium and the dicalcium silicate slag removed, and fresh briquets introduced immediately. The Pidgeon process is used and funds for the proving of the method up to the pilot-plant stage were furnished by Bobjo Mines, Ltd., one-third owner of Dominion Magnesium Co., Ltd. The cost of the plant ($5,000,000) was borne by the Canadian Government, and production is supervised by Wartime Metals Corporation. Dominion Magnesium Co., Ltd., is a private concern incorporated to build and operate the plant without fee or profit.

Exclusive Canadian and United States rights to the Blackwell-Turner high-frequency induction process for the production of magnesium have been granted to the International Industrial Research Corporation of Freeman, Ontario, by the Lancashire Metal Subliming Corporation, Ltd., of Liverpool, England. Plans are to produce the metal from olivine or serpentine at a point near adequate ore deposits and power. Facilities are also planned for the production of magnesium castings, extrusions, forgings, and sheet. Magnesium Devel-

Digitized by Google

opment Co., Ltd., was formed in 1942 under a British Columbia charter with an authorized capitalization of 100,000 shares at a par value of $1 a share.

France.—Output of magnesium is controlled by the Pechiney, Ugine, and Bozel-Maletra concerns, which produce the metal from dolomite and Mediterranean sea-water brine. Production is reportedly being expanded with active cooperation of the Germans, who are supplying funds through the Aero-Bank, the Paris branch of the German Bank für Luftfahrt, A. G.

Germany.—Deutsche Magnesit, A. G., founded in 1929 at Salzburg, has been transferred to Munich, where its magnesium-production activities will be associated with those of Oesterreichische Magnesit, A. G. A new research organization will be formed jointly with I. G. Farbenindustrie, A. G., and will be known as Studiengesellschaft für Metallgewinnung, G. m. b. H. This research group will study the patents of J. März covering thermal reduction of calcined magnesite by carbon and by calcium carbide. Germany has two main sources for the production of metallic magnesium at its disposal—the potash mines in Hanover and Saxony and the magnesite deposits in Bavaria and Austria. These sources can supply all the raw material that the expanded German magnesium industry can use; the limits on expansion are thus not due to a raw-material shortage but to shortages of labor, power, and equipment.

Hungary.—According to a report from the official German news agency, the Hungarian State Iron, Steel, and Engineering Works has obtained a license from I. G. Farbenindustrie, A. G., for the production of metallic magnesium. The new works, the location of which has not been announced, will be operated by a company known as the Hungarian Magnesium & Elektron Co.

United Kingdom.—The Lancashire Metal Subliming Co. is reported to have started the production of magnesium from magnesite using a direct thermal reduction of the oxide. Calcined magnesite is mixed with a reducing agent and heated by high-frequency induction coils to a temperature above the sublimation point of the metal. The metallic vapor is then collected and crystallized under reduced pressure. The Minister of Aircraft Production issued Magnesium Control Order 4 late in 1942, providing a standardized price for all unfabricated magnesium and magnesium alloys and reducing the price of powder to 4s. a pound for all grades. Controlled prices for billets and slabs were also specified.

SUMMARY

Under the use limitations in effect during 1942 the total supply of antimony in all forms, although less than in 1941, was more than adequate to meet military and essential civilian requirements. As in 1941, the supply came largely from Mexico and Bolivia. Imports were augmented by a greatly increased domestic production that helped measurably in alleviating a rather tight situation. By the first part of 1943 stocks had been built up to the point where antimony was classed as a material available in sufficient quantity to be used as a substitute for more critical metals in the strategic minerals list.

The relatively high price for ore in effect at the end of 1941 continued with but little change throughout 1942, owing largely to informal Government control through the Office of Price Administration. The 50- to 55-percent ores quoted at $2.00 to $2.15 per short-ton unit, New York, at the beginning of 1942 were priced at $2.10 to $2.20 at the close of the year. The quotation for domestic metal—14.00 cents per pound, New York, on January 1, 1942—increased to 16.049 cents by the end of the year. This latter figure includes the 3-percent excise tax effective December 1, 1942. The average price of 15.55 cents in 1942 compares with 14.00 cents for both 1940 and 1941.

Domestic production of antimony ore increased 102 percent over 1941, and the metal content gained 143 percent—an indicated rise in the average grade from 35 percent in 1941 to 42 percent in 1942. The antimony content of antimonial lead produced from all classes of foreign and domestic ores increased 10 percent over the 1941 figure and was the largest recorded since 1928. The contents of the total production of antimonial lead at primary refineries from all raw materials—scrap and domestic and foreign ores—increased less than 1 percent but was still the largest since 1929. Although primary antimony available for consumption decreased 20 percent, actual consumption of antimony, including primary material and antimony recovered from the treatment of scrap, was probably the same or even

Digitized by Google

somewhat more than in 1941. Stocks of metallic antimony at producers' plants, as reported to the Bureau of Mines, decreased from 730 tons on December 31, 1941, to 477 tons on December 31, 1942—a continuation of the down trend noted in 1941. A small increase in metal production at the Kellogg (Idaho) electrolytic plant augmented by an appreciable addition to the total supply from the new electrolytic plant at Big Creek (Idaho) was insufficient to offset a slight decline

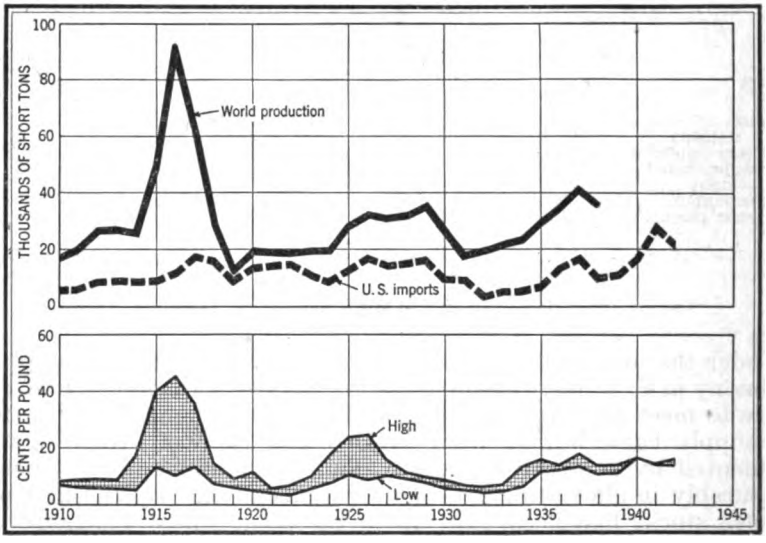

FIGURE 1.—Trends in world production, 1910–38, and United States imports and New York price of antimony, 1910–42.

in the much greater output at Laredo, Tex. No metal was produced by the Los Angeles smelter in 1942.

WAR AGENCY REGULATIONS

The most outstanding effect of Government control on the antimony industry during 1942 was indicated by the reclassification of antimony from group II to group III of the Material Substitutions and Supply List of strategic minerals, effective February 1, 1943. As compiled by the War Production Board, Conservation Division, this list, divided into three groups, reflects the relative essentiality and the current relative supply status of materials useful to the war program. Group I includes critical materials, supplies of which are insufficient for existing war demands; group II—essential war materials, supplies of which are in balance with immediate demand; group III—materials available in significant quantities, which are particularly recommended as substitutes for critical materials.

On March 30, 1942, allocation control over antimony was ordered by the Director of Industry Operations of the War Production Board, with issuance of General Preference Order M–112, effective May 1. Under this order deliveries of antimony were strictly controlled, and all forms of antimony (except alloys containing less than 50 percent by weight of antimony) were placed under complete allocation. Subsequently on July 11, 1942, Order M–112 was amended to allow up to 50 tons a month of contained antimony in ore or concentrates to be delivered by domestic producers, including Alaskan producers, without restriction. Order M–112 was again amended on March 8, 1943. No change was made in the 50-ton limit on the permissible antimony content of unallocated ores and concentrates, but the limit on unallocated deliveries of antimony metal and alloys (50 percent or more antimony contained) was raised from 25 pounds to quantities up to 2,240 pounds. Restrictions were also relaxed to permit the use of greater amounts of antimony in battery grids, in nonacid resisting enamels, and in other antimonial lead uses. An additional indirect curtailment in the use of antimony was effected by the War Production Board Order M–38–c of January 10, 1942, which restricted the use of lead. This order was subsequently relaxed because of the easier supply position.

Because of informal Government control through the Office of Price Administration, the price of antimony showed no change during 1941 and the first months of 1942. The price of 14.00 cents per pound, New York, in effect at the beginning of 1942 was allowed to advance to 15.955 cents on March 23 for small case lots; this was subsequently adjusted upward to meet an advance in freight rates. On April 28, antimony metal was placed under the General Maximum Price Regulation. Effective December 1, a 3-percent excise tax was placed upon property transportation, and being payable by the consumer the quoted price of 16.049 cents reflected this action.

On April 7, 1942, the Metals Reserve Co. agreed to resell antimony ore imported from Bolivia in accordance with a schedule of prices acceptable to the Office of Price Administration. Similarly, on April 27 the War Production Board, in cooperation with the Office of Price Administration, worked out a schedule of informal maximum prices for importers of Mexican antimony ore who applied to the War Production Board for import licenses. Effective May 11, 1942, antimony ores and concentrates were excepted from the General Maximum Price Regulation.

Digitized by Google

DOMESTIC PRODUCTION

MINE OUTPUT

Output from 31 operating antimony mines in 1942 more than doubled that of 1941 from 37 properties and established a new record. The marked gain was due almost entirely to increased output from the Yellow Pine mine in Idaho. In addition, mines containing ores that are produced principally for their value in other metals, mainly gold, silver, copper, and lead, have augmented the supply of antimony for domestic consumption. A large proportion of this increased supply in 1942 resulted from the operations of the Bunker Hill & Sullivan Mining & Concentrating Co. plant at Kellogg, Idaho, and the new Sunshine Mining Co. plant at Big Creek, Idaho.

In 1942, 6,980 short tons of material, containing 2,944 tons of antimony, classed as antimony ores and concentrates were produced compared with 3,460 tons containing 1,214 tons of antimony in 1941. Upon the basis of antimony content the record total for 1942 was 143 percent higher than in 1941 and 40 percent above the previous record of 2,100 tons produced in 1915.

Alaska.—The Stampede mine, Kantishna district, was the only antimony property reporting shipments in 1942. Although the mine was reportedly acquired by Earl Pilgrim early in 1942 from Morris P. Kirk & Son, Inc., production data for 1942 were submitted by Kirk as owner and operator.

Several other antimony properties were prospected and developed in 1942, but no definite figures on production or shipments, if any, were obtained. The Hi Yu Mining Co. was reported to be developing a deposit on Fairbanks Creek near Fairbanks, and a property owned by Sam Gamblin at the head of Tok River reportedly has a good showing of stibnite ore.

In the latter part of the year the first shipment of antimony ore, amounting to 16 tons assaying 38.09 percent antimony, was received at the Fairbanks purchasing depot of the Metals Reserve Co. operated by the Territorial Department of Mines.

California.—The Bishop mine in Inyo County produced and shipped antimony ore in 1942. Smaller shipments came from two additional properties in Inyo County and two in San Benito County. Some ore was produced in less than 1-ton lots.

Production for the State amounted to 68 tons of ore containing 29 tons of antimony, an increase over the 51 tons of ore containing about 15 tons of antimony in 1941.

Idaho.—Not only was Idaho the principal producer of antimony ores and concentrates in 1942, but the total was greater than the entire United States output for any previous year. It amounted to 6,225 tons containing 2,715 tons of antimony; the Yellow Pine mine, owned and operated by the Bradley Mining Co., produced 5,950 tons containing 2,597 tons of antimony. This mine is the largest single source of the metal in the United States. The Antimony Ridge mine, owned and operated by United Mercury Mines, is the second-largest antimony property in Idaho and took second place in the United States in 1942.

In addition to antimony ore, large amounts of antimony came from ores classified as silver ores, copper ores, and others not included in this report as mine output of antimony. The Coeur d'Alene Mines

Digitized by Google

Corporation of Burke and the Sunshine Mining Co. of Kellogg, both produced substantial tonnages of approximately 20-percent antimony concentrates from silver-copper-antimony ore. Production from the former was shipped to the Bunker Hill smelter, whereas concentrates from the latter were treated at the company electrolytic plant built in 1942 for the express purpose of processing such material into antimony metal.

Montana.—Production of antimony ores in Montana increased in 1942 to 280 tons containing 51 tons of antimony from the 1941 total of 113 tons containing 43 tons of antimony. This gain is due largely to the development, by the Sunshine Mining Co., of the Burns antimony district, Sanders County, between Burke, Idaho, and Thompson Falls, Mont. This district embraces a wide section of the Bitterroot Range at the head of Prospect Creek, the main mineralized outcrop occurring along a flat-bedded structure for several miles. Until acquired by Sunshine, under lease, the Prospect Creek deposits had been prospected sporadically for several years with only partial success. Mines and claims reported to have been active were the Stibnite Hill, Eureka, Ellis, and Interstate.

Nevada.—Although the number of reportedly active antimony properties was less than in 1941, the total was greater than in any other State. Nearly every section of the State was represented; and the producing counties, in order of descending importance in 1942, were: Pershing, Nye, Washoe, Lander, Humboldt, and Mineral. There were 11 producers of more than 1 ton; but the average size of the operations was small, and the average grade of the ore was low. Total 1942 production for the State was 305 tons containing 96 tons of antimony—a drop from the 1941 total of 691 tons containing 146 tons of antimony.

Oregon.—Production and shipments of antimony ore in 1942 were made from the Jay Bird mine in Jackson County and the Gray Eagle (Koehler) mine in Baker County. The latter property, in the Virtue district near Baker, was a producer during World War I.

Washington.—The Lucky Knock mine in Okanogan County was the only property to report production and shipment of antimony ore in 1942.

SMELTER OUTPUT

In 1942 primary antimony for shipment to others was produced from foreign and domestic ores at three plants in the United States: Bunker Hill & Sullivan Mining & Concentrating Co., Kellogg, Idaho; Sunshine Mining Co., Big Creek, Idaho; and Texas Mining & Smelting Co., Laredo, Tex. In addition, metallic antimony was again produced by the American Smelting & Refining Co. at its Omaha (Nebr.) plant. This material was used for conversion into other products and was not sold as metal.

The Harshaw Chemical Co. produced no antimony metal at its El Segundo (Calif.) plant in 1942, the output being restricted to antimony oxide. In September 1942, the full-size electrolytic antimony plant of the Sunshine Mining Co., under construction earlier in the year, went into limited operation. This followed the successful experimental operation of a pilot plant from December 1, 1940, to June 1, 1942. Although the plant capacity is rated at approximately 100 tons of metal a month, production by the end of 1942 and during the first quarter of 1943 had not reached capacity owing to a shortage of under-

Digitized by Google

ground labor at the company mines. The greater proportion of the output is from antimony concentrates from tetrahedrite ore, the balance being from company-mined low-grade stibnite ore.

Imports of antimony ore in 1942 amounted to 50,021 short tons containing 20,946 tons of antimony compared with 41,662 tons in 1941 containing 19,386 tons of metal, an increase of 8 percent in terms of antimony content. Industrial receipts of foreign antimony in the United States in 1942 amounted to 48,005 tons of ore compared with 40,434 tons in 1941. These totals are 96 and 97 percent of the total amount imported. The difference in each instance can be accounted for by the usual lag between reporting imports on one hand and receipts on the other, plus the variable tonnage of material in transit at the end of the year which is not statistically counted in the receipts on that date. Receipts exceeded consumption in 1942, and stocks of antimony ore increased 67 percent (gross weight). In 1941 the reverse was true, and stocks decreased 56 percent. Receipts gained 19 percent over 1941, and consumption of 44,944 tons (containing approximately 20,000 tons of antimony) in 1942 was 3 percent less than the reported consumption of 46,211 tons (containing 20,530 tons of antimony) in 1941. The following table shows industry stocks, receipts, and consumption of foreign antimony ore upon the basis of gross weight.

Consumption and stocks of foreign antimony ore in the United States, 1940–42, gross weight in short tons

	1940	1941	1942
Stocks at beginning of year	7,775	10,323	4,546
Received during year	34,530	40,434	48,005
Consumed during year	31,982	46,211	44,944
Stocks at end of year	10,323	4,546	7,607

Production of antimonial lead at primary refineries is shown in the accompanying table. The figures cover only part of the total antimonial lead production, as large quantities are produced at plants that operate exclusively on scrap, and some hard lead is made by mixing antimony and soft lead.

Antimonial lead produced at primary lead refineries, 1938–42, in short tons

Year	Production	Antimony content				
		From domestic ores	From foreign ores [1]	From scrap	Total	
					Quantity	Percent
1938	24,123	1,871	209	729	2,809	11.6
1939	21,995	929	179	923	2,031	9.2
1940	29,762	1,915	162	867	2,944	9.9
1941	40,237	2,586	372	552	3,510	8.7
1942	51,762	2,396	871	257	3,524	6.8

[1] Includes lead ores, antimony ores, and metallic antimony.

SECONDARY PRODUCTION

A large part of the total antimony available for consumption each year in the United States is recovered in the treatment of secondary nonferrous metals. The production of antimony from secondary metals in 1942 totaled 18,200 tons—a 16-percent decrease from the 21,629 tons produced in 1941. Primary antimony available for consumption in the United States in 1942 totaled 23,852 tons. Total antimony available was therefore 42,052 tons, including 57 percent primary and 43 percent secondary; comparable proportions in 1941 were 58 and 42 percent.

Refined metallic antimony is rarely, if ever, produced from scrap metals, the output being in the form of lead-base and tin-base alloys. Most of the plants treating scrap metals containing antimony consumed some other antimony materials, including antimony ore or metallic antimony, for the purpose of adjusting the antimony content of the products. Much of the production is in the form of antimonial lead returned directly to the storage-battery trade. Antimony oxide, sodium antimonate, and other compounds are also produced from scrap metals. Additional information on secondary antimony is given in the chapter on Secondary Metals—Nonferrous.

DOMESTIC CONSUMPTION

Data on the consumption of primary antimony in the United States, based upon quarterly surveys conducted by the Bureau of Mines in 1942, are not yet available in complete form summarizing the entire year. Upon completion this information will be published in a supplemental release. However, an approximate idea of the trend of consumption can be obtained from the following table, which shows the annual supply available for consumption.

Primary antimony available for consumption in the United States, 1938–42, in short tons [1]

	1938	1939	1940	1941	1942
Domestic antimony recovered in antimonial lead	1,871	929	1,915	2,586	2,396
Imports for consumption (antimony content):					
Antimony ore	8,322	9,448	15,733	19,386	20,946
Needle or liquated [2]	63	160	79	447	365
Compounds [3]	336	138	4	2	(4)
Type metal, etc	355	121	191	202	35
Regulus	821	1,045	209	7,469	127
Total available	11,768	11,841	18,131	30,092	23,869
Exports under draw-back	211	232	176	98	[5] 17
Available for consumption [6]	11,557	11,609	17,955	29,994	23,852

[1] Excludes domestic antimony recovered as miscellaneous alloys, oxides, and other compounds.
[2] Content estimated at 70 percent.
[3] Content estimated at 80 percent.
[4] Less than 1 ton.
[5] January to June, inclusive.
[6] Figures are low owing to somewhat incomplete data concerning some items of domestic production.

Primary antimony available for consumption in 1942 decreased 20 percent below the total for 1941 but was 33 percent over 1940. Imports of ore continued to advance; and domestic production, even though still comparatively small, increased to more than twice the

Digitized by Google

1941 total in terms of antimony content. Data on the amount of antimonial lead used in making storage batteries during 1942 are not yet available. This battery metal so used, containing 4 to 12 percent antimony, probably was less than the 131,000 tons consumed in 1941 as reported by the American Bureau of Metal Statistics. Most of the antimony recovered in battery metal is from scrap, though a substantial amount of new metal is added to raise the alloy to the required antimony content.

An important use of antimony is in white-base antifriction bearing metals. According to the Bureau of the Census, shipments of this material produced for sale and for plant consumption in 1942 totaled 22,091 tons—a 33 percent decrease from 33,146 tons in 1941. The manufacturers reporting data that give the above totals represent almost the entire industry. As is true of so many metals during the present war, the decreased consumption does not necessarily indicate lessened importance; rather it reflects relative scarcity of materials coupled with regulatory conservation measures.

Less antimony was used in making chemicals in 1942 than in 1941, the production of oxide and other compounds decreasing 18 percent to 11,950 short tons (preliminary figure) containing approximately 9,703 tons of antimony. Figures on the production of compounds in the 4 preceding years, with the estimated antimony content in parentheses, are as follows: 1941, 14,588 tons (11,590); 1940, 10,211 tons (8,223); 1939, 7,668 tons (6,188); 1938, 4,393 tons (3,539). Nearly all this material was made from foreign ores. Oxide, the most important compound, is used extensively in paints, lacquer, synthetic enamel, porcelain enamel, and glass. A rapidly growing use for oxide, particularly as a war material, is the treatment of canvas and other textiles against rotting and fire.

PRICES

The price of domestic brands of antimony was quoted at 14.00 cents a pound for less than carlots in New York during January and February 1942, the same as throughout 1940 and 1941. On March 23 the quotation was listed at 15.955 cents by authority of the Office of Price Administration. Effective April 13, the price was adjusted to 16.013 cents to meet a 6-percent advance in freight rates, and this adjusted price remained unchanged until December 28, when the quotation was raised to 16.049 cents to include the 3-percent excise tax on transportation effective December 1 and payable by the buyer for delivered metal. These prices were still unchanged by the end of May 1943. The average 1942 price for domestic antimony was 15.55 cents (l. c. l. ex store, New York). Very little Chinese metal was available in 1942, and the quotation of 16.50 cents, in effect since November 1939, remained unchanged in 1942 and was the same at the end of May 1943; the price was nominal.

Prices for English regulus (minimum, 99 percent antimony) and foreign regulus (spot deliveries from warehouse) remained unchanged throughout 1942 at £120 and were the same at the end of May 1943.

[1] From daily issues of American Metal Market, except 1938 and 1939, which were taken from Metal Statistics, 1940, p. 529.
[2] Metal Statistics, 1943, p. 543. [3] Nominal.

Quotations for antimony ore on January 1, 1942, according to E&MJ Metal and Mineral Markets, were as follows: "Per (short-ton) unit of antimony contained, at New York, 50 to 55 percent, $2.00@$2.15; 58 to 60 percent, $2.15@$2.25; 60 to 65 percent, $2.25@$2.35. London, 60 to 65 percent, 14s. 9d. per long-ton unit." These prices fluctuated slightly throughout the first months of 1942 but by April steadied to $2.15@$2.20, $2.20@$2.30, and $2.30@$2.40 for the lower, intermediate, and higher grades at which they remained until December. Prices were lowered slightly in December, the quotations being $2.10@$2.20, $2.15@$2.20, and $2.20@$2.30 for the three different grades. These were unchanged by the end of May 1943. The London price for the higher grade ore decreased from the opening quotation to 12s. 6d. by August, advanced slightly to 12s. 9d. in September and decreased again to 12s. 6d. in October, at which point it remained unchanged by the end of May 1943. Prices were nominal.

FOREIGN TRADE[1]

The following tables show imports and exports of antimony and antimony products.

Antimony imported for consumption in the United States, 1938–42

Year	Antimony ore			Needle or liquated antimony		Antimony metal		Antimony oxides and other compounds	
	Short tons	Antimony content		Short tons	Value	Short tons	Value	Short tons	Value

Estimated antimony content in type metal, antimonial lead, and other alloys imported for consumption in the United States, 1938–42, in short tons [1]

Year	Type metal and antimonial lead	Other alloys [2]	Total	Year	Type metal and antimonial lead	Other alloys [2]	Total
1938	[3] 59	296	355	1941	202		202
1939	59	62	121	1942	35		35
1940	191		191				

[1] For details of gross weight and values, see imports shown in Lead chapter of this volume.
[2] Chiefly in special antimony-lead alloys containing high percentage of antimony.
[3] Type metal only.

Foreign antimony (regulus or metal) exported from the United States, 1938–42

Year	Short tons	Value	Year	Short tons	Value
1938	711	$96,836	1941	70	$19,690
1939	58	16,736	1942	(1)	181
1940	276	75,440			

[1] Less than 1 ton.

Imports of antimony ore in 1942 again came principally from Mexico and Bolivia. The total from Mexico was 24 percent more than in 1941, and Bolivian exports to the United States gained nearly 4 percent. The small tonnage of needle or liquated antimony, credited from China, came from bonded warehouse, as there was no actual importation of Chinese antimony in 1942.

In addition to the exports of foreign metal reported in the last table above, 17 tons were exported in finished products under the draw-

Digitized by Google

back provisions of the tariff law from January to June, inclusive; draw-back exports amounted to 98 tons in all of 1941 and 176 tons in 1940.

WORLD PRODUCTION

Data on world production of antimony during the war years since 1938 are incomplete, although additional information has become available for 1939 and 1940 since the figures were last published in the Antimony chapter, Minerals Yearbook, Review of 1940. Although data from countries that supplied 54 percent of the world total in 1938 indicate an 86-percent increase over that year in total world production during 1942, estimates by the Bureau of Mines place the total world mine production of antimony during 1942 at about 50,000 short tons (recoverable antimony content in ores mined). Of this amount the United Nations controlled or had access to approximately 70 percent.

World production of antimony, 1937–42, by countries, in metric tons [1]

REVIEW BY COUNTRIES

Algeria.—Antimony has been found in several localities in the Department of Constantine in Algeria, but reserves are meager. The most important mine is the Hamminate-Sanza, 19 miles southeast of Constantine. The Taya-Khenez mine, 25 miles east of Constantine, ranks second in antimony production. Both of these properties are controlled by the Soc. Nouvelle des Mines de la Lucette. Although potential monthly production of concentrates has been estimated at 200 tons, production for the first 4 months of 1942 was only 331 tons, averaging 35 percent antimony.

Argentina.—Antimony production in Argentina is small, and production figures for 1942 are not available. Part of Argentina's supply of antimony is secured as a byproduct of the lead ores imported from Bolivia. Mines are small and in the mountains of Jujuy and La Rioja Provinces.

Australia.—The March 1943 issue of Mineral Trade Notes, published by the Bureau of Mines, gives the most recent available information on the antimony industry in Western Australia. The section concerning antimony is quoted in full:

> The lode carrying antimonial ore at the Wiluna mines, the chief producer of antimony in Western Australia, is nearing depletion, and other sources are being sought. Many antimony occurrences have been examined but were found suitable only for individual operations. The Blue Spec mine, 15 miles east of Nullagine, offers prospect of reasonable production; and the Federal Government, on recommendation of the State Government, has advanced the company £A15,000 for expanding operation. The mineralized area is 11 miles long and has been opened at a number of places, six localities showing good shoots of antimonial ore. Reserves of proved and probable ore total 17,000 long tons averaging 17 dwt. of gold a ton and 3 percent antimony. The antimonial concentrate obtained assayed 56 percent antimony and 5.5 ounces of gold. The company plans to sink a new main shaft 300 feet deep and open a new level. An adjoining lease will be developed.

Bolivia.—Mining for antimony in Bolivia started as early as 1903, and since that time Bolivia has become the world's second largest producer. The antimony deposits are scattered throughout various Provinces, with the most important near Tupiza in the Department of Potosí and Challapata in the Department of Oruro. Most of the mines are small and are worked intermittently by individual operators depending largely upon the market price of the ore.

Exports of antimony in 1942 reached 17,642 metric tons (content in ore) as compared with 14,870 tons in 1941. On March 18, 1942, the Metals Reserve Co. of the United States contracted with Bolivian antimony producers for all antimony and antimonial lead concentrates produced from February 1 to December 31, 1942, except for material sold to Great Britain and Argentina and for domestic consumption in Bolivia. The established price ranged from $1.85 to $2.21 a short-ton unit, f. o. b. Pacific ports, depending on the grade of ore. Exports of concentrates to the United States through the Antofagasta consular district during the first 11 months of 1942 totaled 7,960 metric tons.

Canada.—The Austin Antimony Syndicate reportedly drilled its property south of Wabigoon, Ontario, in 1942 in a search for antimony. The deposit, originally trench-sampled for gold, showed a 10-percent stibnite content, and assays of more recent samples show even a higher antimony content. Bulk samples were shipped to Haileyburg for testing by the Wah Chang Corporation in New York. The deposit is approximately 250 feet long and about 10 feet wide.

Digitized by Google

China.—China reportedly still has under its control the bulk of the antimony mines that in pre-war years made it the largest producer of antimony in the world. Official Chinese statements indicate that the annual production amounts to about 7,500 tons. A plan mapped out in 1940 by the Ministry of Economic Affairs provided for the production of 1,000 metric tons of antimony in the Szechwan-Sikang area in 1940 and for 1,500 in 1942. With the closing of the Burma Road early in 1942, contract antimony shipments to the United States through the Metals Reserve Co. stopped. Presumably some metal has been getting through to Russia, although no data indicating the extent of such trade are available.

Cuba.—Antimony occurs in the MacKinley area in the northwestern part of the Isle of Pines, and should the need for antimony become great enough to warrant prospecting and mining of the ore this deposit could be developed. The Gaudalupe mine about 13 miles west of Nueva Gerona on the Isle of Pines was originally located for gold about 20 years ago. No work was done, and the claim lapsed. The same area was relocated in 1939 for antimony. The Antimony Co. of Cuba, S. A., was formed, but only a few tons of surface ore were mined. It is reported that $70,000 has been spent in development since February 1941.

Honduras.—Mineral Trade Notes, September 1942, published by the Bureau of Mines, gives the following information concerning antimony developments in Honduras:

> Casa Uhler, S. A., shipped 5 tons of antimony ore to the United States in February. Ore was obtained from the property of Sr. Hector Lainez at Suyatel, approximately 50 kilometers from Tegucigalpa. Casa Uhler, S. A., has contracts with other suppliers and will make additional shipments in the future.

India.—Exploration within the past 2 years has revealed sources of antimony in India sufficient to justify the installation of a plant to treat and refine the ores.

Japan.—The latest information available is that Japan proposed a semigovernmental antimony company to increase production. This was necessary because Japan produces only a fractional amount of antimony to meet its needs and Bolivian exports to Japan had been cut off.

Mexico.—Mexican production of antimony in 1942 amounted to 11,695 metric tons contained in antimony ore and a small quantity of antimonial lead ore, a 5-percent increase over the 1941 total of 11,132 tons. Exports in 1942 totaled 11,283 tons compared with 10,734 tons in 1941.

A detailed description of the antimony deposits and mines of Mexico may be found in Minerals Yearbook, 1941, as abstracted from the November 20, 1941, issue of Mineral Trade Notes, published by the Bureau of Mines.

The decreased production and exports during the latter part of 1942 are partly attributable to the change in operating methods at the Lejocotes mines of the Compañia Minera de Oaxaca, near Tlaxiaco, Oaxaca. The conversion from underground to open-pit mining, accomplished with the financial aid of the Board of Economic Warfare, should be completed early in 1943. As a result, output in 1943 is expected to increase.

Morocco.—The annual production of antimony for both Algeria and Morocco totals less than 1,000 tons. Production figures for the

Digitized by Google

first 4 months of 1942 list 131 tons of 60-percent concentrates for Morocco. Stocks on May 1, 1942, were 715 tons. The ore is an antimony-lead sulfide occurring in veins in Carboniferous schists. The small reserves are being worked at Gouard ou Fellous and at Tafoudeit near Ouldjet in Soltane. For the past 10 years the annual production has ranged from 100 to 200 tons of antimony concentrates; however, potential production is estimated at 150 tons per month.

Peru.—Estimated production of antimony ores in Peru totaled 3,548 metric tons containing approximately 1,550 tons of antimony in 1942 as compared with 2,813 tons containing 1,565 tons of metal in 1941. Exports from Peru in 1942 totaled 2,557 metric tons of ore and concentrates, containing 1,247 tons of antimony, and 6 tons of antimony bars containing 90 to 95 percent metallic antimony.

Although antimony is produced chiefly by the Cerro de Pasco Copper Corporation, mining is done largely by small producers. There are about 70 small antimony mines in Peru, scattered throughout the Departments of Puno, Tima, La Libertad, Huánuco, Ancash, Junin, and Huancavelica. The deposits of the Puno district, which supply half of the total output of Peru, are reportedly large but are not fully developed and produce only part of their potential total. The antimony occurs as concentrations of stibnite in quartz veins traversing belts of slate and schist. The mines are generally worked without mechanical equipment by the most primitive methods.

The new Cerro de Pasco Copper Corporation plant for treating Cottrell dust began operations in a small way in August 1942. As certain metallurgical problems remained to be solved at that time, it was thought that several months would elapse before the plant would be operating properly and at capacity.

Turkey.—Stibnite is mined in the Turhal region southwest of Amasya.

In 1941, the last year for which figures are available, Turkish production of antimony totaled only 120 metric tons (antimony metal content), but as development of small mines progresses the annual output should increase. In 1940, 638 tons of antimony concentrates were produced, of which 395 tons were exported to France and 243 tons to Japan. Production of concentrates in 1939 totaled 1,300 tons.

Domestic production	795	Prices	799
Foreign trade	797	World aspects of cadmium industry	800

GENERAL STATEMENT

Cadmium was in strong demand during 1942 for the protective plating of armament parts and by the end of the year was considered the fifth most critical nonferrous metal. Primary production increased only 2 percent in 1942, but new recovery units were installed that will boost the 1943 output appreciably. Cadmium was placed under priority control by the Office of Production Management January 17, 1942 (Order M–65)—amended by the War Production Board June 24 to provide for direct Government allocation. A ceiling price on cadmium at 90 to 95 cents a pound was established by the Office of Price Administration January 19, 1942 (Schedule 71).

Salient statistics of the cadmium industry in the United States, 1938–42, in pounds

	1938	1939	1940	1941	1942
Production (primary)	4,294,400	4,790,500	6,363,600	7,233,500	7,370,969
Imports (metal)	22,582	309,874	27,491	147,378	53,298
Exports	(1)	(1)	387,118	171,858	283,630
Consumption	[2] 4,100,000	[2] 5,900,000	6,178,000	7,766,000	7,659,000
Stocks (year-end)	(1)	(1)	2,844,200	2,610,643	2,408,992

[1] Data not available. [2] Apparent consumption.

DOMESTIC PRODUCTION

Primary cadmium production established a new record in 1942 as the result of a 2-percent increase over 1941. Producers' shipments also advanced, but imperceptibly. The geographic distribution of primary cadmium production, based upon location of plants that produced metal or compounds (not upon origin of cadmium-containing ores), was as follows in 1942: 70 percent from 4 plants in four Western States, 20 percent from 10 plants in seven Central States, and 10 percent from 8 plants in four Eastern States. Cadmium is obtained only as a byproduct in the recovery of the common nonferrous metals, particularly zinc. Cadmium output will be stepped up in 1943; according to an estimate by the Board of Economic Warfare, 31 percent will come from domestic zinc-lead concentrates, 19 percent from imported Mexican flue dust, and 50 percent from imported zinc concentrates.

Cadmium produced and shipped in the United States, 1938–42, in pounds

	1938	1939	1940	1941	1942
Production:					
Primary:[1]					
Metallic cadmium	4,077,961	4,411,530	6,154,200	6,937,931	7,323,346
Cadmium compounds (Cd content)[2]	216,400	[3] 379,000	209,400	295,600	47,623
Total primary production	4,294,400	[3] 4,790,500	6,363,600	7,233,500	7,370,969
Secondary (metal and Cd content of compounds)[3][4]	(5)	([3] 5)	227,900	379,500	316,345
Shipments[6] by producers:					
Primary:					
Metallic cadmium	2,525,666	5,190,273	6,467,260	7,044,417	7,233,043
Cadmium compounds (Cd content)[2]	211,000	[3] 401,200	205,900	265,700	78,059
Total primary shipments	2,736,700	[3] 5,591,500	6,673,200	7,310,100	7,311,102
Secondary (metal and Cd content of compounds)[3][4]	(5)	([3] 5)	227,200	376,500	304,894

[1] Figures showing primary cadmium production for 1940–42 are strictly comparable. The data for 1938–39 are exactly comparable with 1940–42 as to totals, but in the former period the cadmium content of some compounds made from metal is included with the compounds and excluded from the metal.
[2] Excludes compounds made from metal.
[3] Some secondary compounds included with primary compounds; Bureau of Mines not at liberty to publish figures separately for primary cadmium compounds.
[4] Bureau of Mines not at liberty to publish figures separately for secondary cadmium compounds.
[5] Data not available.
[6] Figures for 1938–39 represent sales.

The following companies produced primary cadmium metal in 1942.

	Location of plant
American Smelting & Refining Co.	Denver, Colo.
American Zinc Co. of Illinois	Fairmont City, Ill., and Dumas, Tex.
Anaconda Copper Mining Co.	Great Falls, Mont.
Eagle-Picher Mining & Smelting Co.	Henryetta, Okla.
Harshaw Chemical Co.	Elyria, Ohio.
National Zinc Co.	Bartlesville, Okla.
Neo-Metal & Chemical Corporation.	Whitestone, N. Y.
New Jersey Zinc Co.	Palmerton, Pa.
St. Joseph Lead Co.	Herculaneum, Mo., and Josephtown, Pa.
Sherwin-Williams Co.	Coffeyville, Kans.
Sullivan Mining Co.	Kellogg, Idaho.
U. S. Smelting, Refining & Mining Co.	Midvale, Utah.
U. S. Steel Corporation	Donora, Pa.

Cadmium compounds are produced principally from metal, although some are made directly from primary residues and secondary materials. Total production of cadmium compounds (in terms of Cd content) decreased 48 percent from 1941 as a consequence of conservation measures.

Total production	2,697,318	1,057,600	4,020,965	1,651,400	1,665,887	859,726

[1] Includes cadmium lithopone and cadmium sulfoselenide.
[2] In addition to quantities shown, cadmium oxide consumed in making other compounds shown was produced as follows: 1940, 33,186 pounds (Cd content, 28,700 pounds); 1941, 33,649 pounds (Cd content, 27,500 pounds); 1942, 38,721 pounds (Cd content, 33,881 pounds).
[3] Iodide included with hydrate to avoid disclosure of confidential figures.
[4] Bromide included with hydrate to avoid disclosure of confidential figures.

FOREIGN TRADE [1]

Imports.—All the cadmium metal imported in 1942 came from Belgian Congo and was added to the Government stock pile held by the Metals Reserve Co. Domestic cadmium production is partly from imported flue dust which in 1942 contained 1,723,728 pounds of cadmium—all from Mexico—and in 1941 contained 2,321,426 pounds—1,984,698 from Mexico, 334,137 from South-West Africa, and 2,591 from the Union of South Africa.

Metallic cadmium imported for consumption in the United States, 1938–42

Country	1938		1939		1940		1941		1942	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value
Belgian Congo									53,298	$40,363
Belgium	20,067	$28,815	197,454	$84,904	27,491	$9,520				
Canada			30,068	14,642			136,280	$139,898		
Germany	55	163	50	148						
Italy	2,240	1,406	35,304	14,847						
Netherlands			38,038	12,649						
Norway			6,720	2,822						
Poland and Danzig	220	190	2,240	961						
United Kingdom							11,098	12,166		
	22,582	30,574	309,874	130,973	27,491	9,520	147,378	152,064	53,298	40,363

Exports.—Cadmium exports totaled 283,630 pounds (251,059 of metal and 32,571 in compounds) in 1942 compared with 171,858 pounds (65,851 of metal and 106,007 in compounds) in 1941 and 387,118 pounds (286,529 of metal and 100,589 in compounds) in 1940. These figures were compiled by the Bureau of Mines from exporters (except that the figure for compounds in 1942 was estimated from data for gross weight obtained from the Department of Commerce); corresponding data for previous years are not available. All but an insignificant quantity of the cadmium metal exported in 1942 went to Russia under Lend-Lease agreement.

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

CONSUMPTION AND USES

Consumption.—Domestic consumption of cadmium totaled 7,659,000 pounds in 1942 compared with 7,766,000 pounds in 1941, a 1-percent decline.

Estimated distribution, by uses, of cadmium consumed in the United States, 1940–42

Use	1940		1941		1942 [1]	
	Pounds	Percent of total	Pounds	Percent of total	Pounds	Percent of total
Electroplating	3,692,000	59.8	4,586,000	59.1	6,661,000	87.0
Bearing alloys	1,300,000	21.0	1,504,000	19.4	282,000	3.7
Solders	73,000	1.2	130,000	1.7	201,000	2.7

Photography	5,000	[2]	11,000	.1	3,000	[2]
Other pigments [3]	49,000	.8	134,000	1.7	1,000	[2]
Total pigments and chemicals	832,000	13.5	1,325,000	17.0	417,000	5.4
Total cadmium consumed	6,178,000	100.0	7,766,000	100.0	7,659,000	100.0

[1] Distribution based in part on data from War Production Board.
[2] Less than 0.1 percent.
[3] Includes plastics, textiles, artists' colors, etc., and some unclassified.

Electroplating.—The most important use of cadmium in the United States is as a protective coating for steel. Of the cadmium consumed in electroplating in this country in 1942, according to the War Production Board, aircraft took 42 percent, ordnance 24 percent, communications 7 percent, automobiles and tanks 6 percent, ships 5 percent, and electrical equipment 3 percent. To relieve the cadmium shortage, many parts whose specifications formerly called for cadmium plating are now galvanized, but there is little agreement regarding the extent to which zinc can be substituted for cadmium.

Alloys.—Certain bearings containing over 95 percent cadmium and small quantities of nickel, silver, and copper are made for heavy-duty applications. Of the cadmium bearings produced in 1942, according to the War Production Board, aircraft took 45 percent, automotive vehicles 31 percent, rolling mills 12 percent, ships 11 percent, and industrial motors and ordnance 1 percent. Solders made of cadmium and various proportions of silver, lead, and zinc are being used more widely and are helping to conserve tin supplies. The addition of about 1 percent cadmium to copper trolley wire improves strength and wear resistance without seriously reducing electrical conductivity. Low-melting alloys containing 4 to 25 percent cadmium are used as a filler in bending thin-walled tubing, as a material for making spotting fixtures and jigs, and as a constituent of fire-detector systems, sprinkler apparatus, and valve seats for high-pressure gas containers.

Digitized by Google

Compounds.—Cadmium sulfide and cadmium sulfoselenide are standard agents for imparting bright resistant yellow and red colors, respectively, to paints, ceramics, inks, rubber, leather, and other products. Papers coated with cadmium sulfide act as mustard-gas detectors. Cadmium nitrate is used in white fluorescent lamp coatings; the oxide, hydrate, and chloride in electroplating solutions; the carbonate in ceramics; and the halides in photography.

Toxicology.—The causes, effects, and prevention of cadmium poisoning, based upon a study of the 345 cases reported to date, were summarized by the Public Health Service.[2]

STOCKS

Total stocks of cadmium in the United States declined 8 percent in 1942, owing to reducing of consumers' inventories. Stocks of metallic cadmium held by producers, distributors, and the Government increased 20, 60, and 76 percent, respectively.

Cadmium stocks at end of year, 1941–42, in pounds

	1941[1]			1942		
	Metallic cadmium	Cadmium compounds (Cd content)	Total cadmium	Metallic cadmium	Cadmium compounds (Cd content)	Total cadmium
Producers	452,004	104,339	556,343	544,301	83,360	627,661
Compound manufacturers	53,507	146,814	200,321	11,895	126,736	138,631
Distributors[2]	82,258	15,369	97,627	131,443	28,311	159,754
Consumers[3]	1,536,000	106,000	1,642,000	1,199,000	83,000	1,282,000
Government	114,352		114,352	200,946		200,946
Total stocks	2,238,121	372,522	2,610,643	2,087,585	321,407	2,408,992

[1] Revised figures.
[2] Comprises principally 6 largest dealers.
[3] Partly estimated. Includes some material in process. Excludes stocks of compounds held by pigment and chemical consumers.

PRICES

Cadmium metal was quoted at 90 cents a pound for sticks and 95 cents for anode shapes throughout 1942. This level was established in 1941 through agreement between producers and distributors and the Office of Price Administration and was made mandatory January 19, 1942 (Schedule 71). The order was modified to permit, after June 22 (Amendment 1), sales of metal in small containers (5 pounds or less) at October (1941) price levels and to allow adjustable pricing contracts after October 26 (Amendment 2). The Office of Price Administration fixed ceiling prices on partly used anodes at 94 cents a pound, cadmium oxide at 95 cents a pound, and cadmium scrap at 35 cents per pound of contained cadmium, effective October 21, 1942 (Order 6, Maximum Price Regulation 204). The maximum prices are f. o. b. plant of the Udylite Corporation, Detroit, Mich., which was appointed by the Government-owned Metals Reserve Co. as its agent to assist in the cadmium stock-piling program and in the redistribution of idle or frozen materials.

Shipments of metallic cadmium, as reported to the Bureau of Mines by primary producers, had an average value of 79 cents a pound in 1942 compared with 78 cents in 1941 and 70 cents in 1940. Producers' quotations, according to Metal and Mineral Markets, averaged 90 cents in 1942 compared with 88 cents in 1941 and 80 cents in 1940.

[2] United States Public Health Service, Cadmium Poisoning: Public Health Repts., vol. 57, No. 17, April 24, 1942, pp. 601–612; Reprint 2371, 12 pp.

Digitized by Google

Prices for compounds remained unchanged during 1942. Cadmium sulfide was quoted at $1.10 a pound, cadmium lithopone yellow at 55 to 65 cents a pound, cadmium lithopone red at $0.80 to $1.25 a pound, and cadmium bromide at $1.65 to $1.91 a pound, according to Oil, Paint and Drug Reporter.

WORLD ASPECTS OF CADMIUM INDUSTRY

The United Nations control over four-fifths of the world new supply of cadmium, but nevertheless there were dire shortages of the metal in the United States, Great Britain, and Russia during 1942. Germany got along with about 16 percent of the supply by confiscating stocks in conquered countries, restricting the use of cadmium to solders and and other alloys, and adopting widespread substitution of galvanizing for cadmium plating.

[1] Data not available. [2] Estimated. [3] Exports.
[4] Cadmium content of flue dust exported for treatment elsewhere; represents in part shipments from stocks on hand. To avoid duplication of figures, the data are not included in the total.
[5] Figures cover January to June, inclusive.

Belgian Congo.—Production of cadmium was begun in November 1941 by Union Minière du Haut Katanga as a byproduct of the preliminary roasting of zinc concentrates from the Prince Leopold mine to obtain sulfuric acid. The metal was exported to the United States.

Canada.—The Dominion of Canada produces five or six times its cadmium requirements, and the surplus is exported to the United Kingdom.[3] The Consolidated Mining & Smelting Co. of Canada, Ltd., Trail, British Columbia, and Hudson Bay Mining & Smelting Co., Flin Flon, Manitoba,[4] are the two producers. The output of the latter company was increased in 1942, partly from a 10-ton pilot plant treating stock-piled zinc-copper-cadmium residues. Canadian cadmium consumption in 1940 was 142,019 pounds (64,419 kilograms), 85 percent of which was used in white-metal alloys. Primary cadmium may be bought and sold only under permit from the Metals Controller, according to an order effective June 1, 1942. Metallic cadmium was quoted at $1.30 a pound throughout 1942 by Canadian Metals and Metallurgical Industries.

SUMMARY

The great demand for platinum metals in the military program made 1942 the most important year in the history of the industry. Despite the unprecedented demand, supplies of platinum, palladium, ruthenium, and osmium were ample for both war and nonwar purposes; and with the use of iridium and rhodium in jewelry and other articles of personal adornment prohibited, the supply of those metals was sufficient for war needs. More platinum metals were refined, imported, and consumed in the United States in 1942 than in any other year. Compared with 1941, new platinum metals refined in 1942 (400,327 ounces) gained 162 percent, imports (335,954 ounces) 8 percent, and consumption (as measured by domestic sales—375,812 ounces) 30 percent. The electrical industry, which ranked third as a consumer of platinum metals in 1941, rose to first place in 1942; the chemical industry again was the second-largest consumer; and the jewelry industry, which in peacetime was the largest user of platinum metals, was third in 1942.

Salient statistics of platinum and allied metals in the United States, 1941–42, in troy ounces

	1941	1942		1941	1942
Production:			Stocks in hands of refiners, importers, and dealers, Dec. 31:

[1] Subject to revision.

[2] In 1942 includes 25,403 ounces (17,027 in 1941) of new platinum from domestic sources, comprising 21,063 ounces (15,219 in 1941) derived from crude placer platium, 7 ounces (3 in 1941) from ore, and 4,333 ounces (1,805 in 1941) obtained from domestic gold and copper ores as a byproduct of refining.

Digitized by Google

Despite the greatly increased demand for platinum metals in 1942, prices remained level.

The use of rhodium in the manufacture of jewelry was prohibited by the War Production Board under Conservation Order M-95, effective March 11, 1942. This order was amended on April 1, 1942, to prohibit the use of rhodium alloys, as well as rhodium plating, in the manufacture of jewelry and other articles of personal adornment. Order M-162, as amended and effective October 31, 1942, prohibited the use of platinum and platinum alloys in the manufacture of jewelry.

Figure 1 shows graphically the trend in world production of platinum metals from 1914 to 1942.

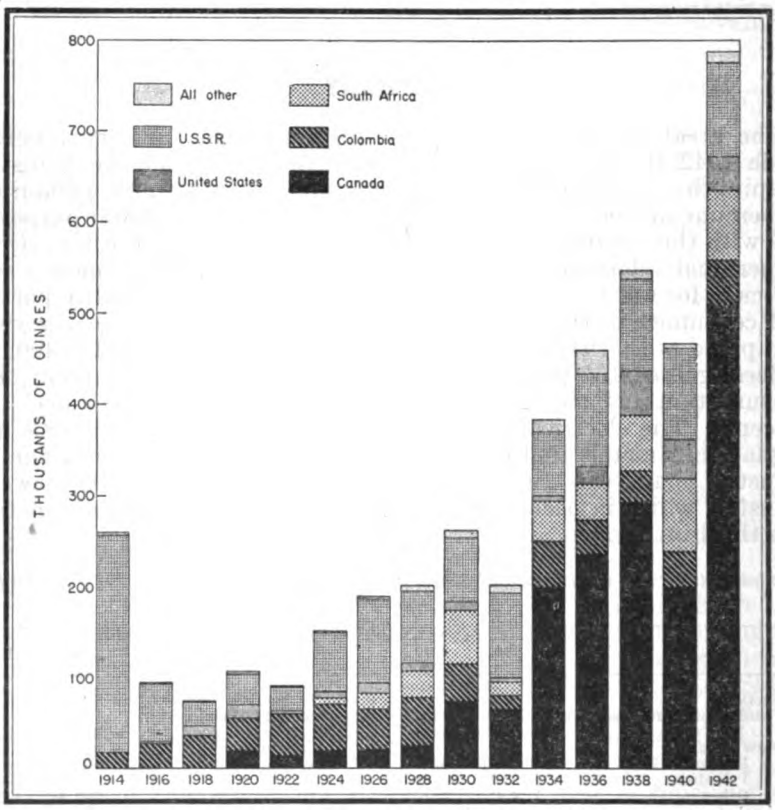

FIGURE 1.—Trend in world production of platinum metals, 1914-42.

CRUDE PLATINUM

Production.—Mine returns for 1942 indicate a production of 22,000 ounces of crude platinum (containing 19,360 ounces of platinum-group metals valued at $1,010,000) in Alaska,[1] 1,200 ounces in California, and 13 ounces in Oregon—a total of 23,213 ounces; comparable

[1] Figures and other information for Alaska from Geol. Survey, U. S. Dept. of Interior. Figures for 1942 subject to revision.

Digitized by Google

figures for 1941 are 24,800 ounces of crude platinum (containing 21,555 ounces of platinum-group metals valued at $1,078,000) in Alaska, 1,300 ounces in California, 41 ounces in Montana, and 80 ounces in Oregon—a total of 26,221 ounces. Production in Alaska came mainly from placer deposits in the Goodnews district of southwestern Alaska; most of it was mined by a large modern dredge and by well-mechanized draglines. In California most of the output of platinum was a byproduct of dredges working gold placers in Butte, Calaveras, Eldorado, Humboldt, Merced, Placer, Sacramento, San Joaquin, Siskiyou, Stanislaus, Trinity, and Yuba Counties. Production in Oregon came from Grant County.

Many gold and copper ores in the United States contain small quantities of platinum metals. In 1942, 9,805 ounces of platinum metals were recovered as a byproduct of refining gold and copper ores, compared with 6,494 ounces in 1941.

Purchases.—Buyers in the United States reported purchases of domestic crude platinum from the following sources in 1942: Alaska, 22,142 ounces; California, 961 ounces; Montana, 2 ounces; and Oregon, 42 ounces—a total of 23,147 ounces (27,017 ounces in 1941). Domestic buyers also reported purchases of 53,661 ounces (38,124 ounces in 1941) of foreign crude platinum or osmiridium in 1942—157 ounces from Australia, 1 ounce from Canada, 53,353 ounces from Colombia, 30 ounces from the Philippine Islands, and 120 ounces from the Union of South Africa.

Prices.—Buyers reported purchases at $28.79 to $75.38 an ounce for domestic crude platinum and $24.05 to $97.55 an ounce for foreign crude platinum or osmiridium in 1942.

REFINED PLATINUM METALS

New metals recovered.—Reports from refiners of crude platinum, gold bullion, nickel, and copper indicate that 400,327 ounces (a new record) of platinum metals were recovered in the United States from such sources in 1942, an increase of 162 percent over 1941. Of the new metals recovered in 1942, 91 percent was chiefly from concentrates from Canada and crude from Colombia, 6 percent was from domestic crude (chiefly from Alaska), and 3 percent was a byproduct of domestic gold and copper ores.

New platinum metals recovered by refiners in the United States in 1942, by sources, in troy ounces

1942	56,150	16,416	1,552	2,493	76,611

Prices.—Quotations[2] on platinum metals remained level during 1942. Platinum was quoted at $36 an ounce, palladium $24, iridium $160 to $175, osmium $45 to $48, rhodium $125, and ruthenium $35 to $40. The quotations on palladium, rhodium, and ruthenium have prevailed for several years.

Properties and uses.—An excellent description of the properties and applications of the platinum metals, with particular reference to the war, has been presented by Wise,[3] from which the following has been drawn.

The chemical applications of the platinum metals, which rank high in immediate importance, are largely a consequence of their catalytic activity, resistance to corrosion, and resistance to oxidation at high temperatures, together with resistance to molten oxides and silicates. Of the catalytic uses, the production of nitric acid by the oxidation of a mixture of synthetic ammonia and air by passing it through a red-hot rhodium-platinum alloy gauze ranks first in wartime importance. The present demand for explosives naturally has led to a large expansion in output of nitric acid, which is used also in production of fertilizers, dyestuffs, photographic materials, plastics, and lacquer, and other chemical and metallurgical processes. Platinum is also used as a catalyst in the manufacture of sulfuric acid by oxidation of sulfur dioxide to sulfur trioxide. Palladium and platinum are excellent catalysts for hydrogenation as well as dehydrogenation. These metals are widely used in the laboratory and are being applied to larger-scale production in the manufacture of various special organic products, including vitamin adjuncts. Ruthenium also has been employed for certain rather special reactions in connection with the synthesis of long-chain hydrocarbons, and osmium tetroxide is an effective hydroxylation catalyst. Palladium has been utilized in supplying extremely pure hydrogen for furnace atmospheres.

Digitized by Google

Pure platinum is universally used as the anode in producing persulfuric acid, and hence hydrogen peroxide, and appears to be the most satisfactory for producing a variety of "per" salts and other highly oxidized materials. Platinum and iridium-platinum also are suitable for insoluble anodes in various electroplating and allied processes, including the recovery of metals from waste solutions. Platinum rupture disks are employed for safe handling of corrosive liquids and gases. Chemical laboratories have long used platinum for crucibles, electrodes, and other equipment, and with the use of microchemical technique many new pieces of platinum equipment have come into production. Use of platinum in plant-scale equipment has awaited the availability of platinum-clad sheets, pipe, rod, and lined reaction vessels, which can now be had in almost any desired size. One of the spectacular recent achievements in the ancient glass industry is the commercial production of fiber glass, which has provided a new and vastly superior insulation for copper wire, a chemically inert fabric, an excellent air-filter medium, and an improved storage-battery separator, as well as a versatile heat-insulation medium. Platinum, because of its resistance to attack by molten glass, made this possible, as the fiber is produced by permitting molten glass to pass through a bank of platinum nozzles from which it emerges in fine streams, which are stretched to produce the minute fibers required. The rayon industry utilizes platinum-gold and rhodium-platinum alloys in a somewhat similar way, as the viscose is forced through small spinnerets made of one of these alloys.

The numerous electrical applications of platinum, palladium, and the other platinum-group metals are based upon their resistance to tarnishing by oxidation or sulfidation, resistance to spark erosion, high melting temperatures, and good mechanical properties. Certain special applications also depend on their resistance vs. temperature relationships or on definite thermoelectric properties. Palladium is used most extensively in the contacts of telephone relays. Platinum, either pure or hardened with up to 10 percent ruthenium or 25 percent iridium, is employed for contacts in voltage regulators, thermostats, and relays, and the two alloys are used for contacts in high-tension magnetos, which are of particular importance in aircraft. Spark plugs equipped with small-diameter platinum-alloy electrodes have found extensive use in the present war owing to their long life and resistance to fouling. The ability to produce platinum wire as small as 40-millionths inch in diameter and its immunity to oxidation have made possible electrical fuses that will blow at a few thousandths of an ampere. Fuses of a different type, also using platinum and palladium alloys, are employed to detonate explosives. Platinum is also employed in resistance thermometers, in temperature-compensating networks of electrical instruments, and in electrical gas analyzers, and rhodium-platinum alloy is the standard high-temperature precision thermocouple. Some of the hard platinum alloys, somewhat similar to those used for tipping fountain pens, are used for special electrical contacts and for bearings in small instruments and magnetic compasses; and some related alloys are used for long-life needles for phonographs. The highly reflective rhodium has proved most satisfactory for surfacing the great searchlight reflectors that have become so important in the war.

Both palladium and platinum are used extensively in dental metallurgy in gold dental alloys to impart superior tarnish resistance,

Digitized by Google

strength, and response to age-hardening treatment. Platinum-base alloys are used in both wrought and cast form for dental restorations of the highest type; palladium-gold alloys are employed for producing the porcelain-to-metal junction in most artificial teeth; and soft platinum-foil matrices are used for producing porcelain crowns and inlays.

In the jewelry and decorative arts platinum is recognized as the ideal metal, particularly for gem-set jewelry. Ruthenium-palladium is now finding much broader application in jewelry. Iridium was formerly the favorite hardener for jewelry platinum but has been supplanted by ruthenium to conserve iridium for war requirements. Both platinum and palladium are beaten into foil in the same manner as gold and are used for about the same purposes.

Consumption.—As pure metals, combined, clad, or alloyed with other metals, the platinum metals are employed in jewelry and dentistry, in the chemical and electrical industries, and for numerous miscellaneous purposes. Sales to consumers in the United States were 375,812 ounces in 1942, compared with 288,397 ounces in 1941.

The most widely used metal of the group is platinum, which constituted 269,176 ounces (71 percent) of the total platinum metals reported sold to consumers in the United States in 1942. The chemical industry, which advanced to first place as a consumer of platinum in 1941, maintained its rank in 1942, accounting for 35 percent (94,025 ounces) of the total sales. The largest outlet for platinum in the chemical industry in 1942 was as a catalyst to produce nitric and sulfuric acids. Important quantities were used also in laboratory ware, rayon spinnerets, and fiber glass. The electrical industry, which ranked third as a consumer of platinum in 1941, was a close second in 1942, taking 34 percent (92,961 ounces) of the total platinum sales. The largest use for platinum in the electrical industry in 1942 was as magneto and other contacts. Sales of platinum to the electrical industry were 228 percent greater than in 1941. The jewelry industry, which dropped to second place in 1941, fell to third place in 1942, taking 25 percent (66,518 ounces) of the total platinum sales. Despite the ban on the use of platinum in jewelry during the last 2 months of 1942, sales were about the same as in 1941. The dental industry purchased 5 percent (13,077 ounces) and miscellaneous uses accounted for the remainder (1 percent, or 2,595 ounces) of the platinum sold in 1942.

Next to platinum, palladium is the most extensively used metal of the group; it constituted 81,460 ounces (22 percent) of the total platinum metals sold to domestic consumers in 1942. The electrical industry was the chief consumer of palladium in 1942, buying 35 percent (28,452 ounces) of the total sold. However, sales of palladium to the electrical industry were 20 percent less than in 1941. A close second in magnitude of consumption of palladium in 1942 was the dental industry (34 percent, or 27,480 ounces), which was followed by the jewelry industry (24 percent, or 19,658 ounces). Sales of palladium to the dental industry declined 13 percent in 1942, but those to jewelers increased 146 percent. Comparatively small quantities were sold for use in the manufacture of chemical ware (5,480 ounces) and for miscellaneous purposes (390 ounces) in 1942.

The consumption of the other platinum metals—iridium, rhodium, osmium, and ruthenium—is comparatively small; it made up 7 percent (25,176 ounces) of the total for the group in 1942. Rhodium

Digitized by Google

and ruthenium (in almost equal quantities) were the most extensively used metals of this group, followed in order by iridium and osmium.

The following table shows sales of platinum metals by refiners, importers, and dealers to consumers in the United States in 1942.

Platinum metals sold to consuming industries in the United States in 1942, in troy ounces

Industry	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total
Chemical	94,025	5,480	5,668	105,173
Electrical	92,961	28,452	12,446	133,859
Dental	13,077	27,480	106	40,663
Jewelry	66,518	19,658	4,275	90,451
Miscellaneous and undistributed	2,595	390	2,681	5,666
	269,176	81,460	25,176	375,812

Stocks.—Stocks of platinum metals in the hands of refiners, importers, and dealers were 303,387 ounces on December 31, 1942, compared with 322,843 ounces at the close of 1941.

Stocks of platinum metals held by refiners[1] in the United States, December 31, 1938–42, in troy ounces

Year	Platinum	Palladium	Iridium	Osmium, rhodium, and ruthenium	Total
1938	71,058	30,071	7,151	9,631	117,911
1939	71,393	29,273	7,000	9,884	117,550
1940[1]	144,302	93,244	32,368		269,914
1941[1]	150,887	138,014	33,942		322,843
1942[1]	160,724	107,383	35,280		303,387

[1] In 1940 figures also include stocks held in the United States by importers from the United Kingdom; in 1941 and 1942 figures also include stocks held in the United States by all importers and dealers.

FOREIGN TRADE[4]

Imports.—Imports of platinum metals into the United States in 1942 established a new record and amounted to 335,954 ounces,[5] a gain of 8 percent over the previous peak year 1941. The principal sources of imported platinum metals in 1942 were Canada (222,685 ounces),[5] Colombia (46,714 ounces), United Kingdom (33,576 ounces), and U. S. S. R. (32,226 ounces). Imports of unrefined platinum (excluding scrap) increased in 1942 to 271,023 ounces (226,951 in 1941), and imports of refined platinum (including scrap) to 46,172 ounces (27,763 in 1941). Imports of refined palladium dropped in 1942 to 9,984 ounces (46,099 in 1941). Imports of refined iridium, osmium, and ruthenium also declined substantially in 1942, whereas there was a marked gain in imports of refined rhodium. Figures on imports in 1942 are subject to revision.

[4] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

[5] The concentrates and residues imported from Canada contain, in addition to platinum, substantial quantities of palladium, iridium, rhodium, and ruthenium, but apparently only the platinum content is recorded by the Department of Commerce.

Exports.—Exports of refined platinum metals and alloys (including scrap) increased to 102,460 ounces in 1942 from 15,405 ounces in 1941. However, the 1942 exports included 97,800 ounces of refined palladium, which was shipped to Canada for storage. On the other hand, the 1941 figures included 8,100 ounces of refined platinum which was reexported to U. S. S. R. Deducting these items, exports of unmanufactured platinum metals in 1942 and 1941 were 4,660 and 7,305 ounces, respectively. Canada and Argentina were the chief foreign markets for platinum metals in 1942.

Platinum and allied metals exported from the United States, 1938–42

WORLD PRODUCTION

Because of restriction on the publication of statistics by certain governments, figures for many countries since 1939 have not been available.

Canada.—According to the Dominion Bureau of Statistics, recoveries of platinum metals from the nickel-copper ores of the Sudbury district, Ontario, were 298,400 ounces of platinum and 226,600 ounces of other platinum-group metals in 1942 (an all-time high), compared with 124,257 ounces of platinum and 97,432 ounces of other platinum-group metals in 1941. Placers in British Columbia yielded 30 ounces of platinum in 1942, compared with 60 ounces in 1941,

Digitized by Google

Colombia.—Colombia exported 49,163 ounces of crude platinum in 1942 (37,349 in 1941). The South American Gold & Platinum Co. produced 25,786 ounces of crude platinum metals in 1942 (30,548 in 1941) and 51,974 ounces of gold (72,582 in 1941). The figures for other operators are not available.

Union of South Africa.—Figures on output of platinum metals are not available for all of 1942, but it is reported that production to the full capacity of the plant proceeded uninterruptedly during the year. The output was shipped to England for refining.

World production of platinum and allied metals, 1937–42, in troy ounces

Stocks	814		

GENERAL STATEMENT

The fading of summer in the Adirondack Mountains brought with it the first large-scale shipments of ilmenite from a mine near Tahawus, N. Y., which is to render the United States self-sufficient in ilmenite—principal ore of titanium. Domestic production of ilmenite tripled in 1942 compared with 1941, but rutile output was held somewhat below its normal level by a plant-expansion program at the Arkansas property. Mining of both titanium minerals is expected to increase greatly in 1943. Ilmenite imports, normally principally from India, slumped in 1942 to a fraction of their former volume, causing consumers to draw heavily on their stocks while awaiting domestic production to reach its stride. In contrast, rutile imports were able to increase in 1942 because of the smaller tonnages involved, a higher shipping priority rating, the relative proximity of Brazilian supplies, and the availability of cargo space on vessels returning from delivery of military supplies to Australia. White pigments and welding-rod coatings took the bulk of the ilmenite and rutile, respectively, consumed in 1942, but both minerals also were consumed in ferrotitanium.

GOVERNMENT CONTROL

Rutile was put under import control by the Office of Production Management, December 26, 1941 (Order M–63), and inventory restrictions on ilmenite were removed by the War Production Board, June 26, 1942 (Amendment 2, Order M–161). Producers of titanium pigments were directed to set aside a pool of 20 percent of their production for allocation by the Office of Production Management, effective December 1, 1941 (Order M–44). Subsequent amendments moved the effective date to January 1, 1942; clarified the original text; effective February 1 increased the allocation pool to 25 percent of the output; and December 9 revoked the entire order. Dealers were verbally requested by the War Production Board in the spring of 1942 to divert to welding-rod and alloy producers the quantities of rutile normally moving to ceramics manufacturers, although no formal order to that effect was promulgated.

Digitized by Google

Price action on titanium pigments first appeared January 3, 1942, when to stem a proposed advance the Office of Price Administration requested stabilization of prices at levels of October 1, 1941. The request was made mandatory March 1, 1942 (Price Schedule 98). Amendments allowed one producer to sell above the maximum price for 2 months, provided for additional means of enforcement, and after December 2 permitted adjustable pricing for long-term contracts.

DOMESTIC PRODUCTION

Ilmenite production in the United States tripled in 1942 compared with 1941 and set a new record, but rutile output decreased 15 percent. The decline was due primarily to a stoppage of Arkansas production during plant enlargement. Ilmenite concentrates shipped in 1942 contained 42 to 52 percent TiO_2, and rutile concentrates ranged from 90 to 94 percent TiO_2. Production and shipments, 1939–42, are shown in the following table. The Bureau of Mines is not at liberty to publish corresponding figures for 1929–38.

Production and mine shipments of titanium concentrates from domestic ores in the United States, 1939–42

Year	Ilmenite			Rutile		
	Production (short tons)	Shipments		Production (short tons)	Shipments	
		Short tons	Value [1]		Short tons	Value
1939	14,602	16,872	$137,042	(2)	(2)	(2)
1940	20,668	20,702	183,686	2,888	2,657	$393,243
1941	23,297	21,526	196,522	3,130	3,431	493,782
1942	(2)	(2)	(2)	2,648	2,649	410,956

[1] Represents cost of production for some producers whose product is consumed by affiliated companies.
[2] Bureau of Mines not at liberty to publish figures.

Arkansas.—The Titanium Corporation sold its rutile property at Malvern, Magnet Cove district, Hot Spring County, in March 1942 to the Titanium Alloy Co. of Arkansas, Inc., subsidiary of the Titanium Alloy Manufacturing Co. The property was inactive from January to September, during which time the concentrating plant was enlarged. In its decade (1932–42) of operation the Titanium Corporation produced 3,771 short tons of rutile averaging 93 percent TiO_2 and shipped 3,621 tons valued at $440,758. In addition, it produced 1,281 tons of rutile averaging 52 percent TiO_2 and shipped 29 tons valued at $583; the remainder was an inventory sold with the plant and will be brought up to commercial grade by the new operator.

Florida.—For 3 years the Riz Mineral Co. (formerly the Consolidated Operations Corporation) has been recovering rutile, ilmenite, and zircon from beach sands near Melbourne, Brevard County. Unworked since 1927, the beach deposits in Duval and St. Johns Counties near Jacksonville will yield large quantities of rutile in 1943, according to present plans of the Titanium Alloy Manufacturing Co.

New York.—The Sanford Lake titaniferous magnetite deposit near Tahawus, Essex County, was opened in 1942 by the Titanium Division of the National Lead Co., which granted a 25-percent interest in the

Digitized by Google

project to the Krebs Pigment & Chemical Division, E. I. du Pont de Nemours & Co., Inc. The mine is known as the MacIntyre Development.[1] Production began in August and by the end of the year was well on the way toward a daily output of 900 short tons of ilmenite concentrates (48 percent TiO_2) and 1,800 tons of magnetite concentrates (64 percent Fe, low P, 9 percent TiO_2, 0.35 percent V) derived from 4,500 tons of ore (16 percent TiO_2). Treatment of the ilmenite involves grinding to pass a 20-mesh screen and concentration by wet and dry magnetic separators. Proved ore reserves total 15 million tons, and probable reserves of the district are prodigious.

North Carolina.—Ilmenite production was begun in January 1942 at Finley, Caldwell County, by the Yadkin Valley Ilmenite Co., subsidiary of the Glidden Co. The feasibility of producing ilmenite from black sands of Albemarle Sound was investigated by the North Carolina State Board of Conservation and Development and E. I. du Pont de Nemours & Co., Inc., Wilmington, Del., but results were not encouraging. A rutile deposit near Shooting Creek, Clay County, from which some shipments were made about 30 years ago, was under development in 1941 by the Southern Minerals Co., Asheville, but most of the property was condemned by the Tennessee Valley Authority for its Chatuge Dam project.

Virginia.—Rutile and ilmenite are produced near Roseland, Nelson County, by the American Rutile Corporation, subsidiary of the Metal & Thermit Corporation. Ilmenite is mined in the same district by the Southern Mineral Products Co., subsidiary of the Vanadium Corporation of America; this property is estimated to contain at least 4 million tons of titanium dioxide.[2]

FOREIGN TRADE[3]

Imports.—Ilmenite imports in 1942 comprised 4,540 short tons from Canada, 2,942 [4] from Australia, 1,287 from Brazil, and 1,165 from India compared with 1941 entries of 156,079 tons from India, 5,725 from Canada, 4,093 [4] from Australia, 3,709 from Brazil, and 969 from Portugal. Imports of rutile in 1942 comprised 4,967 short tons from Brazil, 4,661 [4] from Australia, 111 from French Equatorial Africa, and 35 from French Cameroun compared with 1941 entries of 3,752 [4] tons from Australia and 2,448 from Brazil. Australian concentrates classified as "Zirconium ore" by the Department of Commerce are about half zircon, and the remaining content is largely rutile and ilmenite with some gangue (magnetite, garnet, etc.); the rutile and ilmenite content of such concentrates is estimated and included in the preceding figures. After importation the mixed concentrates are separated into their component minerals by the International Titanium Corporation (subsidiary of the American Rutile Corporation and Ventures, Ltd.), Carteret, N. J.; Orefraction, Inc., Pittsburgh, Pa.; and Titanium Alloy Manufacturing Co., Niagara Falls, N. Y. There were no imports of ferrotitanium, 1941–42.

Titanium concentrates [1] imported for consumption in the United States, 1938–42

Year	Ilmenite			Rutile		
	Short tons		Value of "As reported" [3]	Short tons		Value of "As reported" [3]
	As reported	Total [2]		As reported	Total [2]	
1938	234,275	234,141	$1,018,403	230	364	$26,533
1939	286,576	287,191	1,126,200	442	787	23,170
1940	221,641	223,891	750,590	156	2,164	14,849
1941	166,846	170,689	629,940	3,114	6,291	306,176
1942	7,115	10,369	56,694	6,479	10,465	626,375

[1] Classified as "Ore" by Department of Commerce.
[2] Includes Bureau of Mines estimate of ilmenite and rutile, respectively, contained in Australian zircon-rutile-ilmenite concentrates classified as "Zirconium ore" by Department of Commerce. Data for 1938 are adjusted to apportion Australian zircon-rutile-ilmenite concentrates classified as "Ilmenite" by Department of Commerce.
[3] Value pertains to "As reported" quantity only. Value of remainder included with "Zirconium ore." (See chapter of this volume on Minor Metals.)

Exports.—Exports in 1942 comprised 617 short tons ($117,886) of titanium concentrates, 491 tons ($61,909) of titanium ferro-alloys, 15 tons ($9,938) of titanium tetrachloride, and 9 tons ($3,728) of other titanium compounds.

STOCKS

Stocks of ilmenite were cut in half during 1942 as a result of virtual cessation of imports from India and consequent necessity for consumers to draw heavily on inventories. On the other hand, imports of rutile from Australia and Brazil were not only maintained but appreciably augmented in 1942 so that, even in the face of greatly increased consumption, total inventories of rutile climbed 56 percent. Industry stocks of rutile actually declined 3 percent, but that trend was offset by the stock-piling program of Government-owned Metals Reserve Co.

Stocks of titanium concentrates in the United States at end of year, 1941–42, in short tons

Stocks	1941				1942			
	Ilmenite		Rutile		Ilmenite		Rutile

[1] Includes ilmenite and rutile content of mixed zirconium-titanium concentrates.

CONSUMPTION AND USES

Consumption of ilmenite decreased 6 percent and that of rutile increased 67 percent in 1942 compared with 1941. Ilmenite was used

Digitized by Google

principally in pigments (95 percent) and alloys (5 percent) and rutile in welding-rod coatings (84 percent), alloys (15 percent), and ceramics (1 percent).

Consumption of ilmenite and rutile in the United States, 1941–42, in short tons

Product	Ilmenite		Rutile	
	Gross weight	Estimated TiO_2 content	Gross weight	Estimated TiO_2 content
1941				
Pigments (manufactured titanium dioxide) [1 2]	267,944	147,905		
Welding-rod coatings [1]	58	30	5,461	5,133
Alloys	7,104	3,031	709	673
Ceramics			172	162
Miscellaneous [3]			19	18
Total consumption	275,106	150,966	6,361	5,986
1942				
Pigments (manufactured titanium dioxide) [1 2]	244,465	134,964		
Welding-rod coatings [1]	56	28	8,857	8,326
Alloys	11,802	5,899	1,652	1,526
Ceramics			92	86
Miscellaneous [3]	1,212	521	15	14
Total consumption	257,535	141,412	10,616	9,952

[1] "Pigments" include all manufactured titanium dioxide, consumption of which in welding-rod coatings was 1,700 short tons in 1941 and 4,900 tons in 1942.
[2] Partly estimated.
[3] Consists of ilmenite used as a steel flux and rutile used in lamp-electrode coatings and as a steel deoxidizer.

Titanium pigments.—Manufactured titanium dioxide obtained from ilmenite is used as a white pigment, principally in paint, varnish, and lacquer but also in paper, linoleum, rubber, coated textiles, leather, printing ink, soap, and cosmetics. Nonpigment applications of manufactured titanium dioxide include ceramics and welding-rod coatings. Domestic production of titanium pigments in 1942 receded from the high levels of 1941 at about the same rate as lead pigments and registered the second-best year to date. The output was double that of 1938 and was more in tonnage and twice as large in dollar volume as any other white pigment. Titanium white paints are noted for a high degree of opacity (covering power), reflectance (brightness), whiteness, and durability.

Welding-rod coatings.—Some 321,000 short tons of titanium-coated welding rods were produced in the United States in 1942 compared with 152,000 tons in 1941. According to Iron Age, the quantity of all types of welding rods produced in October 1942 was a little over 35,000 tons. Of this amount 60 to 70 percent was being used in shipbuilding to replace riveting with welding, thereby reducing steel requirements for cargo ships by 10 percent.[5] Titanium shields the arc from oxidation during welding and produces a brittle slag that protects the cooling weld deposit; it is usually added to coating compositions as rutile, manufactured titanium dioxide, or ilmenite.

Titanium alloys.—Ferrocarbontitanium (15–20 percent Ti, 3–8 percent C) is a powerful deoxidizer in steel melts, and ferrotitanium (18–45 percent Ti, 0.1 percent C max.) is added to steel to refine the grain, to

[5] Oliver, Frank J., Welding—Given Tremendous Impetus by War: Iron Age, vol. 151, No. 1, January 7, 1943, p. 127.

Digitized by Google

inhibit intergranular corrosion of stainless steels, and to prevent air-hardening of 5-percent chromium steels. Titanium is added to a number of nonferrous alloys, particularly to aluminum to increase strength and ductility, and is a constituent of a number of complex deoxidizers. The use of the pure metal is limited principally to radio tubes.

Other uses of titanium.—One hundred to two hundred short tons of ilmenite are consumed monthly by the Rustless Iron & Steel Corporation, Baltimore, Md., as a replacement for fluorspar (which, according to the company, emits fumes causing illness to workers) in making titanium-bearing stainless steel. Rutile and manufactured titanium dioxide are used in ceramics, principally to improve the acid resistance of porcelain enamels, to impart colors ranging from cream to brown in pottery bodies and glazes, and to make electric insulators. Consumption of rutile in ceramics was curtailed in 1942, and the quantities thus conserved were diverted to welding-rod coatings and alloys. Small quantities of rutile are used in lamp-electrode coatings of street lights and as a deoxidizer (with aluminum) in special alloy steels. Titanium carbide is a constituent of hard cutting alloys used in machine tools. Titanium tetrachloride is an important smoke-screen chemical.

PRICES

Titanium (in all forms) showed no price changes in 1942. Ilmenite, 60 percent TiO_2, was nominally quoted at $28–$30 a long ton, f. o. b. Atlantic seaboard, according to Metal and Mineral Markets. One consumer was paying $31.50 a ton for Indian material early in the year. Rutile, 94 percent TiO_2, was listed at 8–10 cents a pound. Steel quoted ferrotitanium, ton lots, at $1.23 per pound of contained Ti for 40- to 45-percent grade and $1.35 for 20- to 25-percent grade; and ferrocarbontitanium, 15–20 percent Ti, at $142.50 a short ton for 6- to 8-percent carbon and $157.50 for 3- to 5-percent carbon. Titanium metal, 96–98 percent, was listed at $5–$5.50 a pound. The base price of manufactured titanium dioxide was fixed at 14½–16½ cents a pound by Office of Price Administration Schedule 98, noted under Government Control.

TECHNOLOGY

Titaniferous magnetite analyzing 18 percent TiO_2, from Poplar Lake, Minn., was crushed to minus-48-mesh and treated by hydraulic classification, tabling, and magnetic concentration to yield a product containing 43 percent TiO_2.[6] The effects of titanium in blast-furnace charges and the recovery of vanadium from Sanford Lake ilmenite tailings (titaniferous magnetite) were investigated by the Bureau of Mines, the University of Minnesota, and the National Lead Co.[7] An improved method of making powdered titanium metal was patented.[8]

WORLD PRODUCTION

The United Nations controlled most of the known commercial deposits of titanium in 1942. The Axis countries had access only to mines in Norway and Malaya, unless in addition neutral Portugal sold ore to the Nazis or collaborationist Vichy France contributed material from Senegal. Cameroun concentrates, under protection of the Fighting Free French, were shipped to Great Britain and the United States. Available data on world production of ilmenite and rutile in recent years are shown in the following table.

World production of titanium concentrates (ilmenite and rutile), 1937–42, by countries, in metric tons

[1] Data not available.
[2] Subject to revision.
[3] Bureau of Mines not at liberty to publish figures.
[4] In addition, zircon-rutile-ilmenite concentrates were produced as follows—1937: 73 tons; 1938: 98 tons.
[5] Less than 1 ton.
[6] Exports.

Algeria.—The Keddaradans mine, Palestro district, produced 1,475 metric tons of titanium-zirconium concentrates in the first 4 months of 1942.

Australia.—Mixed rutile-ilmenite-zircon concentrates are produced in New South Wales by Porter & Derrick at Cudgen Headlands, by Metal Recoveries Pty., Ltd., at New Brighton, and by Zircon Rutile, Ltd., at Byron Bay; and in Queensland by Minerals Deposit Syndicate at Little Burleigh. Most of the concentrates are exported in mixed form to the United States; the output of the first-named company goes to the Titanium Alloy Manufacturing Co., of the second to International Titanium Corporation, and of the other two largely to Orefraction, Inc. A little rutile is also produced at Williamstown, South Australia. Some titanium concentrates are consumed in Australia by the Broken Hill Proprietary Co., Ltd., in making ferrotitanium.

Digitized by Google

Brazil.—Production of rutile in Brazil in 1941 was estimated at 2,500 metric tons, principally from Goyaz, Ceara, and Minas Gerais. Concentrates average 70 to 95 percent TiO_2, the higher grades bringing $170 a ton, f. o. b. shipping port.[9] Mining conditions were described.[10]

Cameroun (French).—Rutile exports from French Cameroun in January 1940 were 51 metric tons.

Canada.—Ilmenite is produced at St. Urbain, Quebec. Following an announcement by the Quebec Bureau of Mines that field work indicated favorable opportunities for ilmenite in the Romaine River area, Saguenay County,[11] a massive deposit of ilmenite containing about 37 percent TiO_2 and 53 percent FeO was discovered at Allard Lake, southwest of Havre-St. Pierre, by the Vital Metals Prospecting Syndicate.[12]

India.—Sands of the Malabar coast, State of Travancore, have been the world's principal source of ilmenite; they also yield rutile, zircon, and monazite. Ilmenite production was about 5,100 metric tons in August 1942, compared with a monthly capacity of 32,000 tons, and stocks on hand were 93,400 tons—due primarily to unavailability of cargo space to the United States. There were no inventories of rutile at that time, and the monthly output of 230 metric tons was expected by March 1943 to reach 380 tons, most of which was under contract to the British Ministry of Supply. Ilmenite cost about $5 a long ton, f. o. b. Cochin, but the freight rate to the United States was $28. The three companies that produce titanium concentrates from beach sands are the Travancore Minerals Co., Ltd., Hopkins & Williams (Travancore), Ltd., and F. X. Pereira & Sons (Travancore), Ltd.

Spain.—Plans have been made for the erection of a plant near Gijon, Asturias District, to produce ferrotitanium and other ferroalloys.[13] Workable beach deposits of ilmenite occur in the nearby Districts of Galicia and Coruna and also in the Balearic and Canary Islands.[14]

United Kingdom.—Sales of rutile were subjected to official control May 1, 1942, but legitimate consumers were permitted to order as much as 3 months' requirements at a time.[15] Prices of rutile, f. o. b. consumers' works, were fixed at £54 a long ton for Cameroun concentrates, £42–£50 for Indian concentrates, and £45 for Australian concentrates, according to Metal Bulletin. Indian ilmenite, 52–54 percent TiO_2, was quoted at 28–30 s. per long ton, f. a. s., at the end of 1942.

MINOR METALS

By Allan F. Matthews[1]

SUMMARY OUTLINE

	Page		Page
Beryllium	819	Indium	825
Boron	821	Lithium	825
Calcium	822	Radium and uranium	826
Cerium	823	Selenium and tellurium	828
Columbium and tantalum	823	Thallium	829
Germanium	825	Zirconium	829

BERYLLIUM

Beryl requirements for 1943 were estimated at 7,000 short tons by the War Production Board and at 5,000 tons by the Army and Navy Munitions Board. Beryllium in all forms was placed under import control May 4, 1942 (amendment to Order M–63), by the War Production Board and under complete allocation June 1, 1942 (Order M–160). Copper scrap containing 0.1 percent or more Be was directed to be delivered only to companies specifically authorized by the War Production Board, effective March 1, 1943 (Order M–9–b).

Domestic mine production.—Mine shipments of beryl (beryllium concentrates) increased 70 percent in 1942 compared with 1941 and were the largest on record. Beryl is produced in several Western and New England States as a byproduct in mining feldspar, mica, and other pegmatite minerals. Pennington and Custer Counties in the Black Hills of South Dakota furnished 76 percent of the United States total in 1942 compared with 96 percent in 1941.

Beryl (beryllium concentrates) shipped from mines in the United States, 1938–42

Year	State	Mine shipments		
		Short tons	Value	
			Total	Average per ton
1938	Maine	25	$770	$30.80
1939	Colorado, Maine, South Dakota	95	2,720	28.62
1940	do	121	3,721	30.75
1941	Maine, New Hampshire, South Dakota, Wyoming	158	7,300	46.20
1942	Colorado, Maine, New Hampshire, South Dakota	269	24,188	89.92

Prospecting for beryllium ore was very active in 1942. Most promising is a deposit of helvite (sulfosilicate of manganese, iron, and beryllium) at Iron Mountain, Sierra and Socorro Counties, N. Mex., which was examined in some detail by the Bureau of Mines and Geological Survey and found to contain about a million tons of ore averaging 0.4 percent BeO. This quantity is equivalent to some 35,000 tons of beryl, but its availability depends upon development of suitable concentration methods—a problem now being investigated by the Bureau of

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

Mines and private interests. During 1942 the Bureau of Mines and the Geological Survey examined beryl deposits in Colorado, Connecticut, Idaho, Maine, New Hampshire, South Dakota, and Virginia. Of 131 pegmatites studied in New Hampshire, 61 were found to contain some beryl.[2] A search for additional sources of beryl in the Black Hills was begun by the South Dakota School of Mines under sponsorship of the General Electric Co., Schenectady, N. Y.

Domestic alloy and compound production.—Beryllium-copper master alloys are made by the Beryllium Corporation of Pennsylvania, Reading, Pa., and by the Brush Beryllium Co., Cleveland, Ohio. Clifton Products, Inc., Painesville, Ohio, a producer of oxide, will enter the alloy field in 1943. The facilities of these three companies are being expanded by commitments of $1,900,000, $615,000, and $200,000, respectively, by the Government-owned Defense Plant Corporation. In addition, the Reconstruction Finance Corporation is loaning $500,000 to the Beryllium Corporation of Pennsylvania. Metallic beryllium and beryllium compounds are produced by the Brush Beryllium Co. The Calloy Co., Harbor City, Calif., made some test runs on beryllium oxide early in 1942 but had no commercial output during the year. Recent patents on beryllium production have been summarized.[3]

Foreign trade.—Beryl imports declined 27 percent in 1942 compared with 1941, primarily as a result of an Argentine embargo in effect most of the year. Two-thirds of the 1942 imports were entered in January and December. Exports in 1942 comprised 1,531 pounds of beryllium concentrates, 25,256 pounds ($24,882) of alloys and metal, and 4,778 pounds ($9,274) of compounds.

Beryl imported for consumption in the United States, 1938–42, by countries, in short tons

Country of origin	1938	1939	1940	1941	1942
Argentina	78	384	422	861	701
Brazil		75	377	1,805	915
India and Dependencies (British India)	58				282
Union of South Africa	10		6		38
Total:					
Short tons	146	459	805	2,666	1,936
Value	$5,990	$14,574	$23,865	$143,992	(1)
Average per ton	$41.03	$31.75	$29.65	$54.01	(1)

[1] Data not available.

Stocks.—Inventories of beryl held by the principal miners, dealers, and consumers in 1942 declined from 2,200 short tons January 1 to 1,400 tons December 31. In addition, the Government-owned Metals Reserve Co. began stock-piling beryl in the third quarter and had 725 tons on hand at the end of the year.

Prices.—Beryl prices continued to climb in 1942, and 10- to 12-percent material brought $75–$100 a short ton. Beryllium-copper master alloy (4 percent Be) continued to be quoted at $15 per pound of contained Be by one producer but was listed at $17 by the other. Beryllium metal, 96 percent, was quoted at $47 a pound and beryllium-aluminum at $40 per pound of contained Be, according to American Metal Market.

Digitized by Google

Uses.—The principal application of beryllium is in beryllium-copper alloys (0.1–3.5 percent Be; 0–2.6 percent Co, Cr, or Ag; remainder Cu) fabricated into instrument springs, diaphragms, motor parts subject to wear, and low-sparking tools. Beryllium hardens copper and increases its tensile properties without greatly decreasing electrical conductivity. Beryllium-copper springs have a large amplitude of movement combined with remarkable freedom from elastic drift—properties that enable them to retain stable springiness to a much greater degree than springs made of any other available corrosion-resistant material.[4] Beryllium oxide is used in white fluorescent lamps and special refractories and the metal[5] as windows in X-ray tubes. Interest in beryllium-aluminum continues, but certain fabricating difficulties remain to be solved. Some raw beryl is ground for use in ceramics.

Foreign production.—Argentine beryl output comes from the Provinces of Córdoba and San Luis, but the reserves of the largest producer (Las Tapias mine in Córdoba) are approaching exhaustion. To assure an adequate ore supply for the beryllium oxide-carbonate plant of Sociedad Anonima Berilo Argentina, Juan Ortiz, Province of Santa Fé, an embargo was placed on beryl early in 1942, but the plant experienced operational difficulties and consumed little ore, so the embargo was lifted October 7. Brazilian beryl comes principally from the States of Paraiba and Rio Grande do Norte. A beryl deposit in the Karibib area of South-West Africa was opened in March 1941 by Jooste Lithium Mines, Ltd. Occurrences of beryl in South Africa and Canada have been described.[6] The Beryllium Smelting Co., Ltd., London, was formed in June 1942 "to carry on business of refiners and smelters of beryllium and beryllium compounds."

World production of beryl, 1936–42, by countries, in metric tons [1]

Country [1]	1936	1937	1938	1939	1940	1941	1942

BORON

Boron was a metallurgical hit of 1942, virtually assuring itself high rank in future among the conventional ferro-alloy elements. The effect of boron on steel is to increase hardenability (depth of hardness); greater ultimate strength and elastic limit are also ob-

[4] Carson, Robert W., Springs of Beryllium Copper: Aero Digest, vol. 41, No. 1, July 1942, pp. 150, 153, 272–273.

Digitized by Google

tained.[7] Boron additions of 0.003 percent can substitute for 1 percent nickel, 0.3 percent chromium, 0.2 percent manganese, 0.12 percent vanadium, or 0.1 percent molybdenum.[8] Thus, the incorporation of boron in NE (National Emergency) steels enables the quantities of strategic metals used to be reduced without impairing quality. Not a new discovery, boron in steel has been adopted as a result of fuller realization that only quantities as small as 0.001 to 0.003 percent give optimum results and that much excess causes hot shortness and produces brittle steel. Boron is introduced as ferroboron (10–20 percent B), boron-silicon (Borosil), or one of a series of complex alloys (0.2–2 percent B) such as Grainal, Bortam, Carbortam, Silvaz, or Silcaz.

In cast iron 0.02–0.12 percent boron reportedly increases hardness, refines the grain, and improves wearing qualities, although it also reduces malleability. Boron is a strong deoxidizer, and its use to remove oxygen and nitrogen from copper alloys is said to increase the mechanical soundness and electrical conductivity of castings.

Salts of boron are discussed in the Magnesium Compounds and Miscellaneous Salines chapter of this volume.

CALCIUM

Production of calcium metal was increased in 1942 by the principal producer—the Electro Metallurgical Co., Sault Ste. Marie, Mich. The metal was informally placed under Government allocation control at the beginning of 1943, and a conventional War Production Board order was expected by the middle of the year. Calcium-silicon was subjected to direct allocation by the Office of Production Management July 29, 1941 (Order M–20), which was revised November 29, 1941 (Order M–20–a), and extended indefinitely May 30, 1942 (Amendment 1). Calcium-silicon was imported from Canada in 1942 and from France in 1941. Calcium metal, 97–98 percent, ton lots, continued to be quoted at $1.25 a pound in 1942. According to Canadian Metals & Metallurgical Industries, calcium-silicon, ton lots, was 16½ cents a pound, f. o. b. Welland, Ontario. Metallic calcium, calcium-silicon, and other calcium alloys are used primarily in deoxidizing steel.[9] Additions of up to 0.25 percent calcium in some magnesium castings reduce the heat-treating time and result in an improved surface.

Calcium metal and calcium-silicon imported for consumption in the United States, 1938–42

Commodity	1938		1939		1940		1941		1942	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value

CERIUM

Ferrocerium, the principal pyrophoric (sparking) alloy, was in strong demand during 1941 and 1942 as a constituent of cigarette lighters for our armed forces and particularly for export to the United Kingdom under Lend-Lease agreement. The supply was provided by the Cerium Metals Corporation (formerly American Treibach Chemical Works), Niagara Falls, N. Y., and by Shawinigan Chemicals, Ltd., Shawinigan Falls, Quebec, Canada. Imports of cerium alloys from Canada, only foreign source since the outbreak of war, totaled 11,573 pounds ($65,549) in 1942 compared with 20,190 pounds ($90,948) in 1941 and 462 pounds ($1,611) in 1940. Exports of cerium alloys and metal were 26,016 pounds ($84,739) in 1942. Cerium metal was quoted by Metal Bulletin (London) at £7 5s. a pound and the 52-percent alloy at 35s. a pound at the close of 1942. Ferrocerium is used in cigarette lighters and acetylene-welding torches and as a metallurgical refining agent. Cerium metal finds application in the evacuation of radio tubes. The principal ore of cerium is monazite, described in the Minor Nonmetals chapter of this volume.

COLUMBIUM AND TANTALUM

Columbium (niobium) and tantalum ores were placed under import control by the War Production Board April 9, 1942 (Amendment 4, Order M-63). Full allocation control of tantalum in all forms was instituted May 22, 1942 (Order M-156), and of ferrocolumbium March 25, 1943 (Order M-296). Columbium and tantalum ores (columbite and tantalite) are invariably mixtures, designated one or the other depending on the relative content of Cb_2O_5 and Ta_2O_5. The Government stock pile held by the Metals Reserve Co. included no columbite but 427,756 pounds of tantalite at the end of 1942 and 1,016 pounds of columbite and 321,867 pounds of tantalite March 8, 1943.

Domestic production.—Some 1,000 pounds of tantalite-columbite was produced in South Dakota and Wyoming in 1941–42, but only 200 to 250 pounds was shipped each year. The sole domestic producer of ferrocolumbium is the Electro Metallurgical Co., Niagara Falls, N. Y., and the principal producer of tantalum metal and compounds is the Fansteel Metallurgical Corporation, North Chicago, Ill. Adjunctive to its original plant, the latter company in the name of its subsidiary—the Tantalum Defense Corporation—is erecting facilities for which the Government-owned Defense Plant Corporation has provided $4,225,000.

Tantalite shipped from mines and columbite and tantalite imported for consumption in the United States, 1938–42

Year	Mine shipments of tantalite [1]		Imports			
			Columbite		Tantalite	
	Pounds	Value	Pounds	Value	Pounds	Value
1938	36,189	$35,127	645,141	$228,078	41,706	$30,092
1939	340	200	109,132	37,062	56,561	82,990
1940			595,220	210,526	490,460	258,514

1942	[2] 200	[2] 175	1,762,355	608,917	575,799	481,230

[1] Includes some columbite. [2] Revised estimate. [3] Subject to revision.

Digitized by Google

Foreign trade.—Columbite imports comprised 1,724,800 pounds from Nigeria, 36,422 from Belgian Congo, and 1,133 from Brazil in 1942; and 1,435,312 pounds from Nigeria, 2,914 from Argentina, and 2,229 from Brazil in 1941. Tantalite imports included 309,843 pounds from Belgian Congo, 224,835 from Brazil, 18,971 from Southern Rhodesia, 17,380 from India, and 3,300 from Canada in 1942; they totaled 161,996 pounds from Brazil, 146,904 from Belgian Congo, 64,773 from South-West Africa, 29,574 from Australia, and 217 from the Union of South Africa in 1941. Exports in 1942 comprised 200 pounds ($277) of ferrocolumbium, 266 pounds ($18,475) of tantalum metal and alloys, and 179 pounds ($2,595) of tantalum compounds.

Prices.—Columbite (about 65 percent) was selling at 50–56 cents per pound of contained Cb_2O_5 early in 1943. The Metals Reserve Co. purchased tantalite during 1942 at $1.25 per pound of contained Ta_2O_5 for 40-percent material, $1.75 for 50-percent, $2.15 for 60-percent, and $2.60 for 70-percent material. Ferrocolumbium, 50–55 percent, was quoted by Metal and Mineral Markets at $2.25–$2.30 per pound of contained Cb, f. o. b. Niagara Falls. Columbium metal continued to be listed at $227–$254 a pound and tantalum metal at $65–$73 a pound.

Uses.—The addition of 0.5 to 0.8 percent columbium to stainless steels[10] has been found to improve weldability, creep strength, and impact strength. One application is aircraft exhaust stacks, manifolds, and collector rings. Tantalum is used principally in electronic tubes and carbide tools and as a catalyst in producing butadiene synthetic rubber. Smaller quantities go into corrosion-resistant equipment for chemical plants and into aerial camera lenses. The glass for these lenses is a mixture of tantalum, tungsten, lanthanum, and boron oxides without silica and combines high refractivity and low dispersion, resulting in a lense that can be used at high altitudes with no loss of definition or coverage. Tantalum metal is recommended for skull plates.[11]

Foreign production.—Nigeria produced 623 metric tons of columbite and exported 862 tons in the first 9 months of 1942, according to the War Production Board. The Jantar Nigeria Co., Ltd., principal producer, mined 424 metric tons of columbite and shipped 711 tons during the year ended September 30, 1942; proved ore reserves at that time were 4,800 tons, and the expected output for the 1943 fiscal year was 500 tons, all under contract to American buyers.[12] A pilot plant for producing columbium oxide has been built in England.[13] Belgian Congo was producing about 11 metric tons of tantalite monthly in mid-1942, according to the War Production Board. Brazilian exports of tantalite-columbite were stated by the Board of Economic Warfare to be 94 tons in 1941. Moneta Mines, Ltd., opened a tantalite deposit in 1942 between Malartic and Amos, Quebec, Canada.[14]

GERMANIUM

Germanium in small quantities (often about 0.01 percent) occurs in zinc and copper ores, but it has never been recovered on a commercial scale in the United States. A pilot plant erected by the Eagle-Picher Mining & Smelting Co., Henryetta, Okla., to treat cadmium by-products yielded small quantities of germanium metal, oxide, and chloride during 1942. Uses for germanium are reported occasionally, but none have appeared sufficiently promising to induce the War Production Board to stimulate domestic production or importation from South-West Africa of a quantity of germanium residue obtained as a byproduct of smelting Tsumeb copper-lead-zinc ores. Germanium metal was quoted by suppliers of rare metals at $3–$5 a gram in New York and 19s. 6d. a gram in London at the close of 1942, but commercial grades were available at lower prices.

INDIUM

Domestic production.—Indium metal production in the United States in 1942 increased several-fold over 1941. Virtually the entire 1942 output—byproduct of zinc and lead operations—was produced by the Anaconda Copper Mining Co., although the Eagle-Picher Mining & Smelting Co. had a small pilot-plant yield. Some indium has been produced in past years by the American Metal Co., Ltd., American Smelting & Refining Co., and National Zinc Co., Inc., and these companies marketed some metal from stock during 1942. The Indium Corporation of America, principal distributor, owns a property near Kingman, Mohave County, Ariz., where there is reputedly blocked out 50,000 tons of zinc ore averaging about 2 troy ounces of indium per ton. The increasing demand for indium is expected to result in early exploitation of this deposit.[15]

Prices.—The price of indium metal, commercial grade (98 percent), according to Metal and Mineral Markets was $12.50 a troy ounce during most of 1942 but was reduced to $10 an ounce ($146 an avoirdupois pound), effective December 23. Electrolytic-grade indium (99.9 percent) was reduced on the same date from $30 to $15 an ounce.

Uses.—Cadmium-nickel and copper-lead bearings for aircraft, truck, and marine engines are coated with indium to resist the corrosive action of acids in lubricants, and this application absorbed most of the indium consumed in 1942. The life of bronze bearings in a certain heavy-duty screw machine was lengthened greatly by indium treatment. Additions of 1 to 2 percent indium to lead-silver solders improve coverage, spreadability, and bonding strength.[16] In general, indium coatings 0.0005 to 0.001 inch thick on nonferrous metals improve resistance to corrosion and abrasion and present a lustrous finish.

Foreign production.—The Consolidated Mining & Smelting Co. of Canada, Ltd., Trail, British Columbia, began to produce indium in 1941. Indium has also been produced commercially in Germany, Belgium, and possibly Japan and U. S. S. R.

LITHIUM

Production facilities for lithium metal were greatly expanded during 1942. Nevertheless, supply could not pace demand, so the War

[15] Ludwick, M. T., Indium: Steel, vol. 111, No. 19, November 9, 1942, pp. 80–81, 122–124.
[16] Metal Finishing, Indium Solders: Vol. 40, No. 11, November 1942, pp. 594, 596.

Digitized by Google

Production Board instituted allocation control of the metal and compounds September 1 (Order M–191) and of the ores December 5 (Order M–253). Lithium ores are discussed in the Minor Nonmetals chapter of this volume. Lithium has a strong affinity for gases and impurities in molten metal, and its addition to copper-base alloy melts in the form of lithium-copper (2 percent Li), lithium-zinc (2 percent Li), or lithium-calcium (50 percent Li) results in sounder castings and higher conductivity. The use of lithium as a scavenger in cast iron and steel is also developing. Lithium in small quantities (0.04–0.1 percent) is reported to improve the physical properties of various lead, zinc, aluminum, and magnesium alloys. Addition of 0.12 percent lithium to a silver brazing solder increased fluidity, strength, and melting properties.[17] Lithium metal, 98–99 percent, 100-pound lots, was quoted at $15 a pound throughout 1942, according to Metal and Mineral Markets.

RADIUM AND URANIUM

Industrial radiography absorbed over half of the new supply of radium in 1942, and most of the rest went into luminescent paints. There were virtually no Government controls on the delivery, price, or use of radium and uranium in the United States in 1942; but effective January 26, 1943, the War Production Board prohibited the use of uranium in ceramics (Order M–285). Research on uranium progressed appreciably in 1941–42, and in the interest of secrecy the War Production Board relinquished to the War Department the supervision of supply and distribution.

Domestic production.—Carnotite is mined in Arizona, Colorado, and Utah for recovery of vanadium, radium, and uranium.[18] Grinding tests on these ores were conducted recently by the Bureau of Mines.[19] Increased production of vanadium has yielded large quantities of uranium in concentrates and tailings, but it is not known to what extent these have been processed. The domestic output of radium in 1942 was 2.6 grams, all refined by the Vitro Manufacturing Co., Pittsburgh, Pa. The S. W. Shattuck Chemical Co., Denver, Colo., devoted its facilities principally to molybdenum compounds and thus produced no radium. The two companies had material in stock at the end of 1942 containing about 1 gram of radium each. These companies and the Vanadium Corporation of America (Naturita, Colo.) are producers of uranium compounds.

Foreign trade.—All the radium, radioactive substitutes, and uranium imported in 1941–42 came from Canada, except entries of 100 milligrams of radium from Belgium (originally) and 525,559 pounds of uranium ore from Belgian Congo in 1942 and 53,090 pounds of uranium compounds from Belgian Congo in 1941. Exports in 1942 comprised 1,245 grams ($58,997) of radium-bearing compounds, 2 milligrams ($8) of mesothorium compounds, 543 grams ($1,076) of uranium concentrates, and 426 pounds ($1,827) of uranium compounds.

Radium salts, radioactive substitutes, and uranium ore and compounds imported for consumption in the United States, 1938–42

Year	Radium salts			Radioactive substitutes (value)	Uranium ore		Uranium oxide and salts	
	Grams	Value			Pounds	Value	Pounds	Value
		Total	Average per gram					
1938	38.75	$787,025	$20,300	$5,746	----------	----------	376,708	$520,540
1939	78.631	1,953,820	24,800	966	5	$10	1,439,324	1,197,786
1940	30.311	748,097	24,700	5,650	2,400,198	2,110,927	240,199	388,355
1941	4.412	110,202	25,000	13	----------	----------	387,505	501,370
1942	23.043	377,326	16,400	50	541,307	806,919	377,398	851,098

Prices.—Radium was nominally quoted at $25 a milligram during 1942. Some sales at $25–$27.50 were reported, but probably most were nearer $20 a milligram. Orange or yellow uranium oxide and sodium uranate were listed by Glass Industry unchanged at $1.65 a pound during 1942; black uranium oxide was quoted at $2.55 a pound until December, when the price was reduced to $2.15.

Uses of radium.—Most of the radium in current use is for the treatment of cancer and skin diseases. However, over half of the new supply is employed in radiographic inspection of castings, forgings, and welds. In many instances of both medical and industrial radiography, radium emanations and X-rays can be utilized interchangeably. Radium coatings on watches, gun sights, compasses, and other instrument dials permit observation in the dark. Radium and beryllium mixtures project neutrons for petroleum exploration [20] and scientific research. The number of radioactive specimens tested annually by the National Bureau of Standards gives some index as to demand. Such specimens contained 16,408 milligrams of radium and 2,139 milligrams of mesothorium in 1942 compared with 19,928 and 1,451 milligrams, respectively, in 1941. Mesothorium is a radium substitute obtained from monazite residues. The National Bureau of Standards recently outlined safe practices in handling radioactive compounds in the dial-painting industry (Handbook 27) and gave suggestions for the protection of radium during air raids (Handbook 38). Polonium, a byproduct of radium, is a radioactive element used in spark plugs.[21]

Uses of uranium.—The principal peacetime outlet for uranium is as a colorant in ceramics, but this use was prohibited in January 1943 to assure ample supplies for research on uranium isotope 235 as a source of energy [22] and for consumption in special steels, luminescent paints, photographic reagents, and other chemicals.

Foreign production.—Eldorado Gold Mines, Ltd., reopened its pitchblende mine at Great Bear Lake, Northwest Territories, Canada,[23] in 1942 after a 2-year shut-down. Its refinery at Port Hope, Ontario, continued to operate during the interim on accumulated concentrates and in 1942 reportedly ran close to its capacity of 8 or 9

grams of radium and 40 short tons of uranium compounds monthly. The radium-uranium mine in Belgian Congo, owned by Union Minière du Haut Katanga, remained inoperative in 1942, although a few hundred tons of ore were shipped from stock to the United States. British-owned Urgeirica Radium, Consolidated, produced all of Portugal's output in 1941—330 metric tons of uranium ore (1–1.8 percent U_3O_8) and 772 kilograms of radioactive barium sulfate containing 5.8 grams of radium.

SELENIUM AND TELLURIUM

Domestic production.—Selenium and tellurium production declined 18 and 0.2 percent, respectively, in 1942 compared with 1941, and producers' shipments slumped more than 50 percent. Thus, in 1942 producers maintained their output relatively close to the 1941 peak even in face of a drastic decline in demand, hoping, apparently, that current uses would expand or that the shortage of common metals would promote development of new uses for selenium and tellurium and thereby provide an outlet for their mounting stocks. Some tellurium is a byproduct of lead, but all the selenium and most of the tellurium recovered come from the tank slimes of electrolytic copper refineries. Annual plant capacity for selenium and tellurium production is approximately 750,000 and 300,000 pounds, respectively, but actual capacity for the former is limited by the availability of selenium slimes.

Salient statistics of elemental selenium and tellurium in the United States, 1938–42

Year	Selenium					Tellurium [1]		
	Production (pounds)	Producers' sales [2] (pounds)	Producers' stocks at end of year (pounds)	Imports [3]		Production (pounds)	Producers' sales [2] (pounds)	Producers' stocks at end of year (pounds)
				Pounds	Value			
1938	225,674	166,494	365,400	101,034	$163,598	11,076	26,944	77,300
1939	227,131	345,726	246,800	124,830	193,168	25,234	63,431	39,100
1940	328,731	368,709	206,800	134,429	198,163	85,622	88,996	35,700
1941	620,493	681,650	146,000	197,873	288,161	224,639	239,983	20,400
1942	506,426	316,613	341,900	83,666	127,004	224,132	98,798	145,700

[1] Includes tellurium content of small quantity of oxide.
[2] Bureau of Mines not at liberty to publish value. Quantities for 1942 represent producers' shipments.
[3] Includes selenium salts.

Foreign trade.—Except for an unspecified quantity valued at $5 from the United Kingdom in 1942, all selenium imports in 1941–42 came from Canada. Tellurium is not shown in import statistics, except in combination with other commodities. Producers reported exporting 5,550 pounds of selenium (including Se content of compounds) and 150 pounds of tellurium in 1942 compared with 23,169 pounds of selenium and no tellurium in 1941. Dealers doubtless exported additional quantities.

Prices.—The base price of selenium (black powdered, 99.5 percent) and of tellurium continued to be $1.75 a pound throughout 1942. Glass Industry quoted barium selenite and sodium selenite at $1.40–$1.65 a pound.

Uses.—The largest consumer of selenium is the glass industry, which uses it as a red colorant and (in smaller additions) as a

Digitized by Google

decolorizer. Most of the tellurium supply and some selenium are added to rubber cable coverings to promote resistance to heat, oxidation, and abrasion and to increase resilience. Additions of selenium and tellurium improve the machinability of stainless steels and copper alloys.[24] Formerly made of silver-plated brass, cable connectors of tellurium-copper (combining high machinability and electrical conductivity) are going into aircraft, torpedo boats, tanks, and trucks.[25] Coatings of red selenium on magnesium alloys to resist attack by sea water have found considerable application in Europe. Cadmium sulfoselenide pigments (red, maroon, and orange) were in wide use until the cadmium shortage. Tellurium toughens lead and is now substituting for chromium in the development of wear-resistant surfaces on gears, wheels, and other cast-iron products. Uses of selenium and tellurium are described in a comprehensive paper by several research men at Battelle Memorial Institute.[26]

THALLIUM

Thallium output was stepped up in 1942 by the sole domestic producer, the American Smelting & Refining Co., which recovers the metal as a byproduct of zinc-cadmium operations at its Globe refinery, Denver, Colo. Thallium has been produced in Belgium, France, Germany, and Poland, and cessation of imports from these countries has resulted in a shortage of thallium in the United States. Thallium metal is quoted at $10 a pound by Metal and Mineral Markets and sulfate at $5–$7 a pound by Oil, Paint and Drug Reporter. Most of the thallium supply is consumed in the form of sulfate, an odorless, tasteless poison used in rodent and ant control. Consumption of thallium sulfate was 3,500 pounds in 1942, according to an estimate by the Department of Agriculture. Thallium oxysulfide is sensitive to wave lengths in the infrared and is therefore useful in "dark signaling." Thallium-lead alloys containing 3–65 percent Tl are among the most insoluble alloys known.

ZIRCONIUM

No use or price control was imposed on zirconium in 1942, but the War Production Board placed the concentrates under import control December 27, 1941 (Order M–63). The Government-owned Metals Reserve Co. began stock-piling zirconium concentrates in 1942 and by the end of the year had on hand 4,590 short tons of zircon and 4,156 tons of baddeleyite. The Government purchased zircon only as an inducement to processors to increase the supply of rutile obtained from Australian mixed zircon-rutile concentrates.

Domestic production.—Zircon production in the United States amounted to a few hundred tons in 1942 compared with somewhat smaller quantities in 1941 and 1940, no output in 1929–39, and 3,646 short tons in 1927. The only domestic producer at present is the Riz Mineral Co., which recovers zircon as an accessory of rutile and ilmenite from beach sands near Melbourne, Fla. At the beginning of

Digitized by Google

1942 E. S. Curtis set up a pilot plant on the Fay Placers Mining Co. property, Lincoln, Calif., to determine the feasibility of producing zircon as a byproduct of gold dredging, but the results indicated that such production was not economical at current price levels and the plant was dismantled in May. Tests on concentration of zircon from Oregon beach sands were conducted by the Bureau of Mines.[27]

Foreign trade.—Imports of zirconium concentrates included 18,259 short tons from Australia, 15,283 from Brazil, and 196 from India in 1942 compared with a total of 21,709 from Australia, 5,002 from Brazil, and 963 from India in 1941. The Australian concentrates are nearly half zircon and also contain appreciable quantities of rutile and ilmenite. (See Titanium chapter of this volume for details.) The Brazilian zirconium concentrates are essentially baddeleyite containing 70 to 85 percent ZrO_2. Exports in 1942 comprised 30 tons ($2,104) of zirconium concentrates, 166 tons ($169,729) of zirconium alloys and metal, and 201 tons ($65,975) of zirconium compounds.

Zirconium concentrates and zirconium ferro-alloys imported for consumption in the United States, 1938–42

Year	Zirconium concentrates [1]		Zirconium ferro-alloys	
	Short tons	Value	Pounds	Value
1938	2,093	$62,138	244,126	$13,520
1939	3,433	49,919	799,269	50,169
1940	16,845	252,749	533,055	37,126
1941	27,674	604,744	----------	----------
1942	33,962	817,702	----------	----------

[1] Classified as "Ore" by Department of Commerce. Includes zircon-rutile-ilmenite concentrates from Australia.

Prices.—Metal and Mineral Markets continued to quote zirconium ore, 55 percent ZrO_2, at $60–$70 a short ton, f. o. b. Atlantic seaboard; zirconium ferrosilicon at $102.50–$107.50 a long ton for 12- to 15-percent Zr content and 14–16 cents a pound for 35–40 percent Zr; and powdered zirconium metal at $7 a pound.

Uses.—Most of the zirconium supply goes into ceramics, chiefly as an opacifier in porcelain enamels and pottery glazes but also as a constituent of refractories, electrical and chemical porcelains, grinding balls, and glasses resistant to heat and chemicals. Metallurgically zirconium is a deoxidizer and scavenger; and small additions to certain steels are said to improve hot-working properties, surface characteristics, and impact strength. Zirconium-copper is a promising alloy that combines high heat conductivity and tensile strength.[28] Ductile zirconium metal is used in electronic tubes, lamp filaments, and welding rods, and the metal powder in flares, photoflash bulbs, and blasting caps. In addition to ceramics, zirconium compounds go into white leather, resins, dye extenders, water repellents, and catalysts.

SURVEY OF THE BITUMINOUS-COAL AND LIGNITE INDUSTRY IN 1942

In response to the increased need for coal to keep the war economy moving, the production of soft coal was pushed to an all-time high in 1942 estimated at 580,000,000 net tons, which surpassed the previous peak of 579,385,820 net tons mined in 1918. Owing to the Government program to encourage summer storage of coal, there was less seasonal decline than for any year on record. The regularity of production in 1942 was in striking contrast with 1941. During the first quarter of 1941 production was high to fill orders purchased for storage by consumers in anticipation of possible suspension of mining when the wage contract expired on March 31. Output was largely at a standstill in April pending the signing of a new wage contract.

Production.—The 1942 output—580,000,000 net tons—was a 13-percent increase over 1941. An outstanding feature related to this production was the elimination of seasonal declines, due largely to the Government program urging consumers to build up stocks during the summer. Throughout most of the year production remained well above 11,000,000 net tons per week.

Consumption.—Each of the major classes of consumers except steel and rolling mills used more coal in 1942 than in 1941; the increase

[1] Data for 1942 are preliminary; detailed statistics with final revisions will be released later. Data for 1941 are final.

The collection of statistics on the bituminous-coal industry which before 1937 was conducted by the Bureau of Mines is now performed by the Bituminous Coal Division, U. S. Department of the Interior, Dan H. Wheeler, Director.

Material in this chapter was prepared in the Division's Economics Branch under the supervision of G. A. Lamb, chief. It was completed under the immediate direction of W. H. Young, in collaboration with R. L. Anderson, M. E. McMillan, and R. M. McKinney.

Digitized by Google

ranged from 23 percent for beehive coke ovens to 4 percent for coal-gas retorts. Consumption by steel and rolling mills, for uses other than making coke, declined 4 percent in 1942 compared with 1941.

Changes in stocks.—The reserve supply of coal in the hands of industrial consumers and retail coal yards rose from a total of 62,737,000 net tons at the beginning of 1942 to 85,889,000 net tons at the close. The days' supply of stocks advanced from 40 to 51. Between the same periods stocks on the upper Lake docks declined 1,418,621 net tons, while unbilled coal in cars at the mines or classification yards fell 780,000 net tons.

Distribution.—Shipments of bituminous coal and lignite during 1942 rose substantially above the 1941 level in each of the primary channels of distribution except in Lake Erie loadings, which decreased slightly. Table 9 shows trends in distribution of bituminous coal for

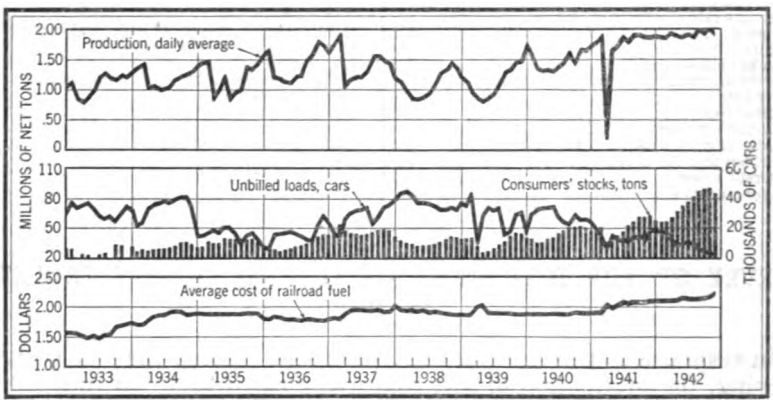

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal and lignite in the United States, 1933–42.

1937–42. Changes in the monthly volume of the more important movements are shown in figure 7.

Mechanization.—Coal loaded mechanically at underground mines in the United States continued to advance sharply during 1941. The quantity of soft coal mechanically loaded expanded from 147,870,252 net tons in 1940 to 186,667,250 in 1941, an increase of 26 percent. The percentage of total underground bituminous and lignite production mechanically loaded increased from 35 in 1940 to 41 in 1941.

Mechanical cleaning.—Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States (exclusive of Alaska) rose from 102,205,186 net tons in 1940 to 117,469,857 in 1941, an increase of 15 percent. There are no mechanical cleaning plants at lignite mines.

Trend of employment.—An estimate of the average number of men employed at bituminous-coal and lignite mines in 1942 indicates a slight rise to 460,000 men from 456,981 in 1941. The estimate is based largely on monthly indexes of employment compiled by the Bureau of Labor Statistics.

Index to capacity.—The potential output upon a 308-day basis was 733,000,000 net tons in 1941. Under the 5-day week, full-time operation is limited to approximately 261 days. The average output per working day was 2,380,321 tons during 1941, which (if applied to 261

Digitized by Google

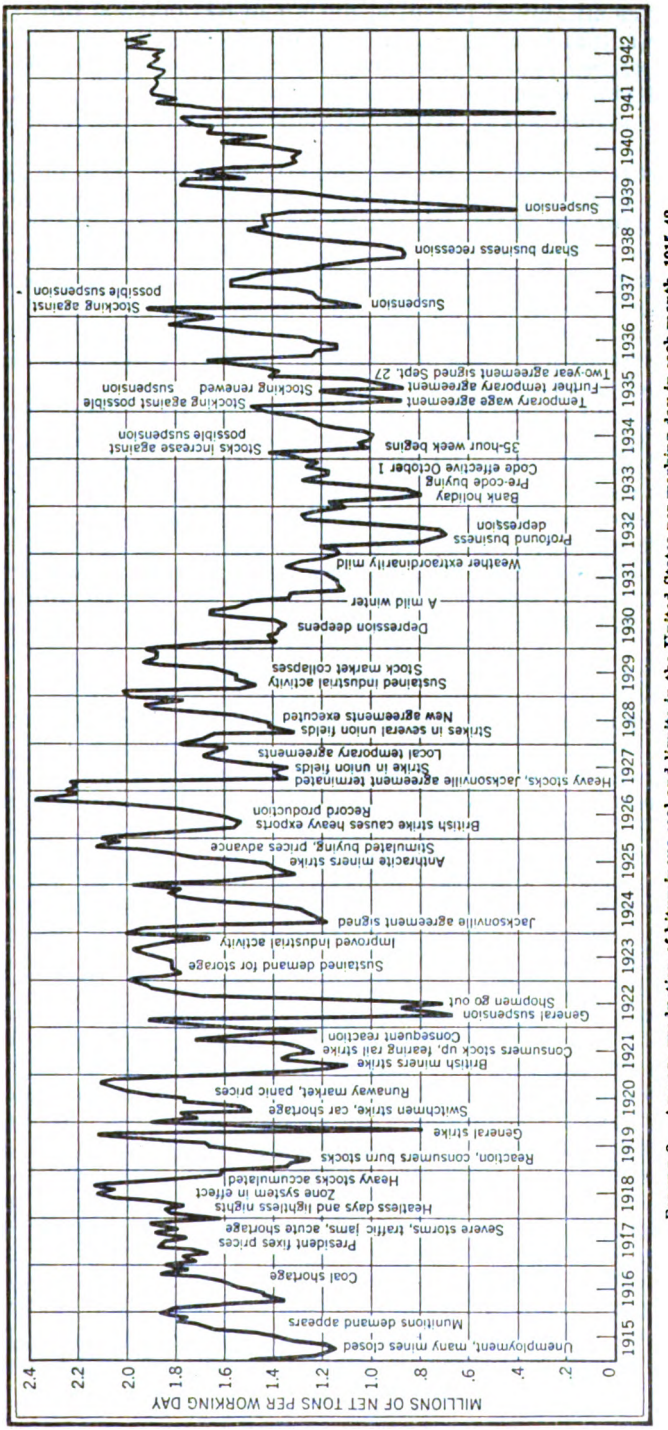

FIGURE 2.—Average production of bituminous coal and lignite in the United States per working day in each month, 1915–42.

Digitized by Google

days) gives an annual potential output of 621,000,000 tons compared with the actual total production of 514,149,245 tons.

Trend of fuel efficiency.—For many years before 1942 there was a steady trend toward increased fuel efficiency. During 1942 this trend was arrested or reversed, and some industries exhibited decreased fuel efficiency (see table 5).

Competition of oil and gas.—Competition of coal with oil and gas in 1942 was overshadowed by the necessity of making the best possible use of the fuels available and satisfying the unprecedented fuel requirements of a war economy. Rationing of fuel oil in the Eastern States was accompanied by extensive conversion from oil to coal, particularly with respect to industrial fuel-burning facilities.

Electric power utilities consumed 6 percent more bituminous coal and 14 percent more gas in 1942 than in 1941, while decreasing their use of fuel oil by 24 percent.

The consumption of coal in 1942 by class I line-haul railroads increased 19 percent over 1941, and fuel-oil consumption by class I line-haul, switching, and terminal railroads increased 23 percent.

In domestic heating the effect of curtailment of the manufacture and sale of certain types of fuel-burning equipment is shown by Bureau of the Census data. Sales of domestic stokers dropped from 158,734 in 1941 to 62,753 in 1942, a decrease of 60 percent; and shipments of domestic oil-burners, boiler-burner units, and furnace-burner units fell from 271,673 to 82,357, a decrease of 70 percent.

SOURCES OF DATA

Bituminous-coal and lignite production statistics for 1942 are preliminary estimates based upon (1) weekly or monthly reports of railroad carloadings of coal and beehive coke by all the important carriers, (2) shipments by river as reported by the United States Army Engineers, (3) direct reports from a number of mining companies, and (4) monthly production statements compiled by a number of local operators' associations and State mine departments. In the estimates for 1942, allowance has been made for commercial truck shipments, local sales and colliery fuel, and small trucking or wagon mines producing over 1,000 tons a year.

The 1941 bituminous-coal statistics were compiled by the Bituminous Coal Division, and 1941 statistics on lignite and certain semianthracite mines in Montgomery and Pulaski Counties, Va., were compiled by the Bureau of Mines. Data for 1941 are final and are based upon detailed annual reports of production and mine operation furnished by the producers. As in previous years, all but a small percentage of the output was covered by the reports submitted. For the remaining output not directly reported, consisting chiefly of small mines, it has been possible to obtain reasonably accurate data from the records of the State mine departments, which have statutory authority to require such reports or, in a few instances, from railroad carloadings.

Final production of bituminous coal and lignite for 1941 was 514,149,245 net tons. This differ slightly from 515,769,248 net tons, as published in May 1943 in Mineral Industry Surveys HSS 309 by

Digitized by Google

the Bureau of Mines. These two figures differ largely because the annual canvass of the Bituminous Coal Division includes only mines with 1,000 tons or more yearly production, whereas the Bureau of Mines canvass is concerned with the production of all mines in which men are employed and hence are exposed to accident hazards incident to mining.

SALIENT STATISTICS

TABLE 1.—*Salient statistics of the bituminous-coal and lignite industry in the United States, 1940–42*

[All tonnage figures represent net tons]

	1940	1941	1942 (preliminary)
Production	460,771,500	514,149,245	580,000,000
Consumption in the United States [1]	431,331,000	492,445,000	540,726,000
Stocks at end of year:			
Industrial consumers and retail yards	50,998,000	62,737,000	85,889,000
Stocks on upper Lake docks	6,998,258	7,777,446	6,358,825
Unbilled loads, at mines or in classification yards [2]	1,298,300	919,700	139,700
Price indicators (average per net ton):			
Average cost of railroad fuel purchased, f. o. b. mines [3]	$1.88	$2.02	$2.13
Average cost of coking coal at merchant byproduct ovens [4]	$4.40	$4.69	$4.97
Average retail price—38 cities [5]	$8.60	$9.15	$9.53
Average railroad freight charge per net ton [6]	$2.22	$2.22	$2.31
Underground loading machinery sold: [7]			
Mobile loading machines (number)	233	367	352
Scrapers (number)	36	8	15
Conveyors, including those with duckbills (units)	1,573	1,800	[8] 1,167
Pit-car loaders (units)	3	10	2
Average number of men employed at mines operating [9]	439,075	456,981	460,000
Fuel-efficiency indicators:			
Pounds of coal per kw.-hr. at electric power plants [10]	1.35	1.34	1.34
Pounds per 1,000 gross ton-miles—railroads [11]	113	111	111

[1] Represents certain classes of consumers only. See table 4 for consumers included.
[2] Association of American Railroads.
[3] Interstate Commerce Commission (class I steam railways, including class I switching and terminal companies) Excludes freight charges.
[4] As reported by coke operators to the Bureau of Mines.
[5] Bureau of Labor Statistics.
[6] Average receipts per net ton of revenue bituminous coal and lignite originated, as reported by the Interstate Commerce Commission.
[7] Young, W. H., Anderson, R. L., Lamb, G. A., and Buch, J. W., Mechanization Sales: Coal Age, February 1943, pp. 86–88; and Min. Cong. Jour., February 1943, pp. 68–70.
[8] Not comparable with previous years; in 1942, loading heads were not counted as a separate unit.
[9] The figures for 1940 and 1941 are based upon reports of mine operators producing over 1,000 tons. The figure for 1942 is estimated from various sources, including the employment index of the Bureau of Labor Statistics.
[10] Federal Power Commission.
[11] Interstate Commerce Commission; includes coal equivalent of fuel oil consumed.

PRODUCTION BY WEEKS AND MONTHS

The following tables summarize the preliminary statistics of weekly and monthly production of bituminous coal and lignite in 1942. The figures are estimates based upon daily and weekly statements of cars of coal and beehive coke loaded by the principal railroads and of shipments over the more important originating rivers. Allowance has been made for commercial truck shipments, local sales, and colliery fuel. The estimates given are based upon the latest information available and differ in some instances from the current figures previously published in the Bituminous Coal Division's Weekly Coal Reports.

For the method used in counting holidays, see the chapter on Coal in Mineral Resources of the United States, 1930, p. 631.

TABLE 3.—*Estimated monthly production of coal in the United States, by States, in thousands of net tons, in 1942*

[Bituminous and lignite figures are preliminary estimates based upon railroad carloadings and river shipments of coal and beehive coke, supplemented by direct reports from a number of mining companies, local coal operators' associations, and detailed monthly production statistics compiled by the State Mine Departments of Colorado, Illinois, Pennsylvania, Washington, and West Virginia. In making the estimates, allowance is made for commercial truck shipments, local sales, and colliery fuel, and for small trucking mines producing over 1,000 tons a year. Where a mine is on the border between two States, the production is accredited to the State from which the coal is extracted, rather than the State in which the tipple is located. The estimates here given differ in a few cases from the current figures previously published in the Weekly Coal Reports]

State	January	February	March	April	May	June	July	August	September	October	November	December	Total

CONSUMPTION

TABLE 4.—*Consumption of bituminous coal and lignite, by consumer class, with retail deliveries in the United States, 1934–42, in thousands of net tons* [1]

Year	Colliery fuel	Electric power utilities [2]	Railroads (class I) [3]	Coke [4]		Steel and rolling mills	Coal-gas retorts	Cement mills [4]	Other industrials [5]	Retail-dealer deliveries	Total of classes shown
				Beehive ovens	By-product ovens						
1934	3,175	31,835	76,037	1,635	44,343	10,898	2,475	3,500	83,798	86,925	344,621
1935	3,103	33,013	77,109	1,469	49,046	11,747	2,245	3,516	91,589	83,990	356,827
1936	3,227	40,029	86,391	2,698	63,244	13,471	1,945	4,771	108,620	94,200	408,596
1937	3,052	42,871	88,080	4,927	69,575	12,853	1,680	5,247	122,410	80,076	430,771
1938	2,493	38,245	73,921	1,360	45,266	8,412	1,644	4,483	92,390	68,520	336,734
1939	2,565	43,979	79,072	2,298	61,216	9,808	1,614	5,274	98,900	71,570	376,296
1940	2,443	50,973	85,130	4,803	76,583	10,040	1,746	5,633	106,280	87,700	431,331
1941	2,489	61,861	97,384	10,529	82,609	10,902	1,659	6,832	120,720	97,460	492,445
1942 [6]	2,807	65,634	115,410	12,907	88,014	10,434	1,721	7,499	131,550	104,750	540,726

[1] These data have been assembled to show changes in consumption of bituminous coal and lignite by such classes of consumers as report currently. The total, including retail deliveries, does not represent grand total consumption in the United States. Bunker-fuel statistics are not available for publication at present. The "total of classes shown" for each year in the above table cannot be reconciled with the calculated consumption obtained by the formula: "Production plus imports minus exports plus or minus net changes in consumers' stocks" due to the omission of bunker fuel; to revisions in data covering production, exports, and imports; and to unavoidable irregularities that occur in reports from respondents who are unable to require that definitions applied and closing dates observed by their accountants are identical with those generally used in the surveys of bituminous-coal and lignite consumption.

[2] Geological Survey and Federal Power Commission. Represents bituminous coal and lignite consumed by public utility power plants in power generation, including a small quantity of coke amounting to approximately 100,000 tons annually.

[3] Association of American Railroads. Represents the consumption of bituminous coal and lignite by class I railways for all uses, including locomotive, powerhouse, shop, and station fuel. The Interstate Commerce Commission reports that in 1941 the consumption for all uses by class I line-haul railways plus the purchases for class II and class III railways, plus purchases by all switching and terminal companies combined, was 103,228,446 net tons of bituminous coal and lignite. Similar data from the Interstate Commerce Commission are not yet available for 1942.

[4] Bureau of Mines.

[5] Estimates based upon reports collected jointly by the National Association of Purchasing Agents and the Bituminous Coal Division from a selected list of representative manufacturing plants.

[6] Subject to revision.

FUEL EFFICIENCY

TABLE 5.—*Indicators of effect of fuel economy on consumption of coal in the United States per unit of performance since the World War of 1914–18*

	Pounds	Reduction from base period (percent)
Steam railroads:		
Pounds per 1,000 gross ton-miles freight service:		
Average:		
1919–20	170	----------
1941	111	34.7
1942	111	34.7
Pounds per passenger-train car-mile:		
Average:		
1919–20	18.5	----------
1941	14.9	19.5
1942	15.1	18.4
Electric public utility power plants:		
Pounds per kilowatt-hour:		
1919	3.2	----------
1941	1.3	59.4
1942	1.3	59.4
Iron and steel—pounds coking coal per net ton of pig: [1]		
1918	3,194	----------
1941	2,525	20.9
1942	2,604	18.5
Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913–42, expressed as percent of coal used for all coke in 1942 [2]	----------	18.5

[1] Includes only savings through higher yields of merchantable coke per ton of coal charged and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are covered in next item.

[2] These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and coking, and to a small extent for automotive fuel.

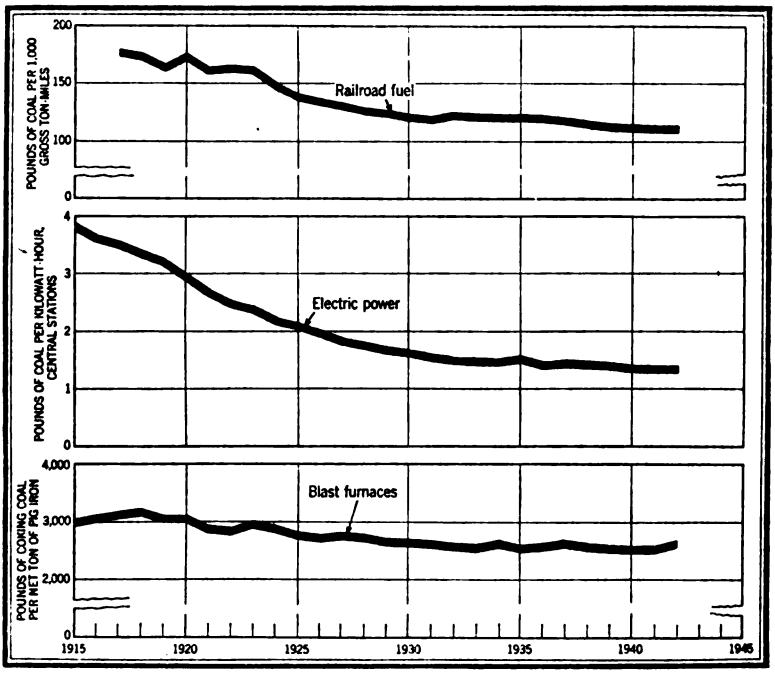

FIGURE 4.—Trends of fuel efficiency in the United States, 1915–42.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER, 1889–1942

According to preliminary data, the total supply of available energy in the form of coal, oil, natural gas, and water power in 1942 was 31,785 trillion B. t. u.—an 8.7-percent increase over 1941 (see fig. 5). The figures are expressed in British thermal units because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Table 6 summarizes the equivalent of each of the fuels in trillions of British thermal units. Water power is represented by the equivalent fuel required to perform the same work. The table covers the years since 1933. Details for 1889 to 1932 are given in Minerals Yearbook, 1937, page 807.

In converting water power to its fuel equivalent, two alternative assumptions have been made. The first, as in previous issues of these tables, assumes a *constant* fuel equivalent of 4.02 pounds of coal for each kilowatt-hour of water power produced throughout the entire period from 1889 to 1942. This factor was selected because it represents, in round numbers, the average efficiency of all central stations generating steam-electric power in 1913, the midpoint of the period under review. The usefulness of the *constant* factor lies in showing the rate at which water power is being developed. It permits direct comparison between the relative increase (in kilowatt-hours of water power) and the corresponding increase or decrease (in tons of coal, barrels of oil, or cubic feet of gas produced). On the other hand, the *constant* factor makes no allowance for the fact that coal and other fuels produced today are used more efficiently than formerly.

Digitized by Google

To throw light on the influence of improving fuel efficiency, a second computation of the energy equivalent of water power has therefore been made. This assumes a *prevailing* fuel equivalent, diminishing year by year, which represents the average performance of all fuel-burning central electric stations for the year in question. This average has declined from about 7.05 pounds of coal per kilowatt-hour in 1899 to 1.34 pounds in 1942. (The *prevailing* factor is thus much above the *constant* factor in 1899 and much below it in 1942.) The *prevailing* fuel equivalent indicates more nearly the quantity of fuel that would have been needed in any one year to generate the same power in a steam-electric station. It should be noted, however, that the ultimate uses to which the water power generated is put often displace fuel burned much less efficiently than in central stations and that in any instance no other important branch of fuel consumption has made advances in fuel efficiency approaching that of the central stations.

As these tables attempt to determine the total energy from all fuels and from water power, the ideal factor for converting water power into fuel equivalent would be the average efficiency of all forms of fuel consumption in each year. No basis for determining such an all-embracing average exists at present, but enough is known to make certain that it would show much less reduction from 1899 to 1942 than did the central stations. For the present, a just comparison of the changing contributions of water power and of fuel to the national energy supply would lie somewhere between the results shown by the *constant* equivalent and the *prevailing* central-station equivalent in these tables.

As in earlier issues of these tables, the figures for oil and natural gas represent the entire production of crude petroleum and of gas. Most of this production does not come into direct competition with coal. Much of the supply of both oil and gas is used in regions of the country, such as California and portions of the Southwest, where coal is available only at unusually high cost because of heavy transport charges. Nearly half of the natural gas is used in the field for drilling or operating oil and gas wells and pipe lines or for the manufacture of carbon black. More than half the oil is used in the form of gasoline, kerosine, and lubricants, for which purposes coal cannot well compete, except at very much higher levels of oil prices. Even these refined products, however, involve a certain measure of indirect competition with coal, for the energy market of the country is becoming more fluid and competitive and a demand that cannot be met by one source of supply tends to fall back on the others.

The subject of interfuel competition is exceedingly complex, and an elaborate analysis and the accumulation of data not now available would be required to determine even approximately how much of any one fuel actually has been displaced either by other fuels or by water power. The present tables do not permit determination of such displacement; their purpose is rather to measure the long-time trends in the total demand for energy.

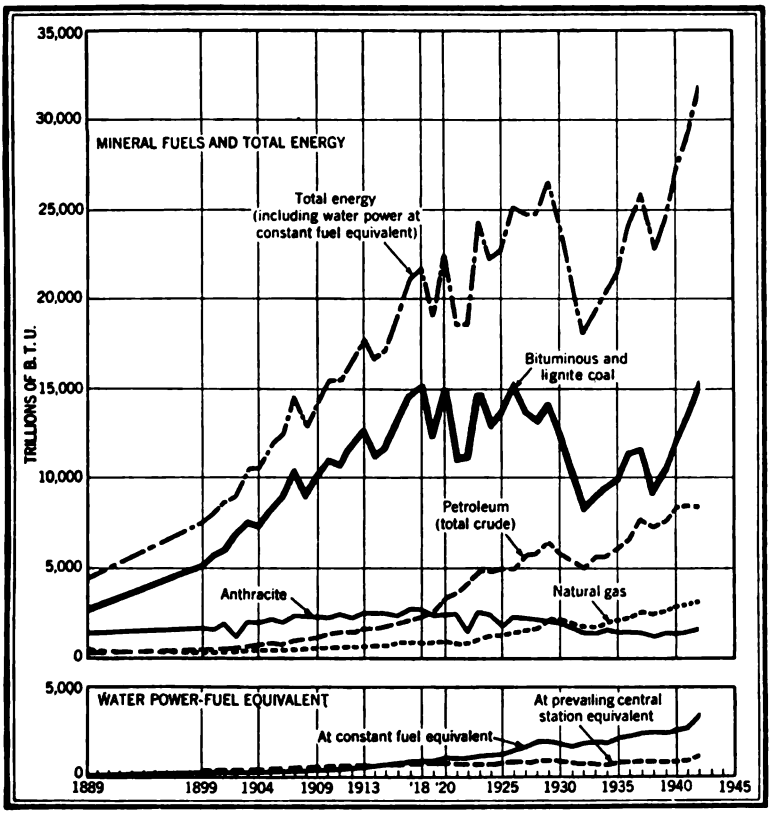

FIGURE 5.—Annual supply of energy from mineral fuels and water power in the United States, 1889–1942.

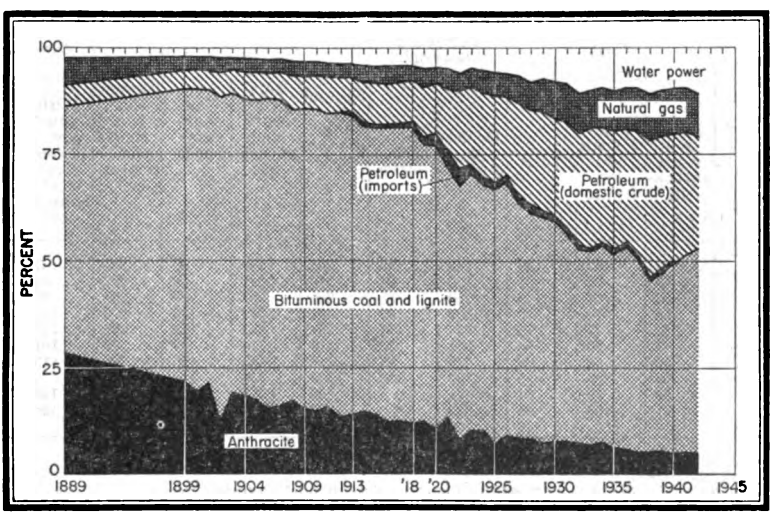

FIGURE 6.—Percentage of total B. t. u. equivalent contributed by the several sources of energy in the United States, counting water power at *constant* fuel equivalent, 1889–1942. If water power is counted at the *prevailing* fuel equivalent of central stations in each year, its proportion is 3.2 percent in 1899 and 3.9 percent in 1942, and the proportions of the other sources of energy are affected accordingly.

1942 [5]	1,631	15,196	16,827	8,313	(6)	3,171	[6] 11,484	[6] 28,311	3,474	1,157	[6] 31,785	[6] 29,468

[1] Comparable data for earlier years in Minerals Yearbook, 1937, p. 807.
[2] The unit heat values employed are: Anthracite, 13,600 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum, 6,000,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as is true of all public utility plants since 1919. Otherwise the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for manufacturers and mines and of 40 percent for public utilities.
[3] Assuming 4.02 pounds per kilowatt-hour, which is average of central-electric-station practice in 1913, the base period used.
[4] Assuming the average central-station practice for each of the years for which data are available, which declined from about 7.05 pounds per kilowatt-hour in 1899 to 1.34 pounds in 1942.
[5] Subject to revision.
[6] Excludes imports of crude petroleum. Figures not available for publication.

TABLE 7.—*Index numbers for relative rate of growth of coal, oil, and water power in the United States, 1933–42* [1]

FINAL BITUMINOUS-COAL AND LIGNITE STATISTICS FOR 1941

Tables 11 to 45 give the final detailed statistics of bituminous-coal and lignite mine operations in 1941. The subjects covered include production, number and size of mines, employment, value, mechanization, and world production.

In accordance with the practice followed by the Bureau of Mines in previous years, the statistics in this report relate to mines having an

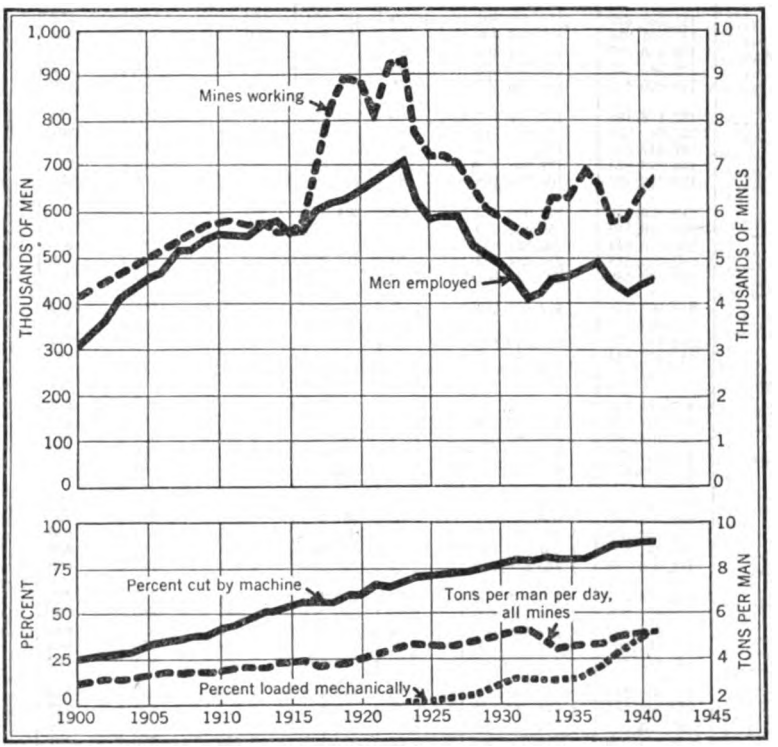

FIGURE 8.—Trends of employment, mechanization, and output per man at bituminous-coal and lignite mines in the United States, 1900–1941.

output of 1,000 tons a year or more and do not attempt to include many small mines producing less than 1,000 tons a year that sell their output by wagon or truck.

These statistics include, for convenience and historical comparison, the small output of anthracite and semianthracite produced outside Pennsylvania and the production of lignite.

1941	216	20	27	5.20	1,125	89.0	40.7	22.9	10.7

[1] Percentages for the years 1890 to 1913, inclusive, are of total production, as a separation of strip mine and underground production is not available for these years.

[2] For the years 1906 to 1926, inclusive, these percentages are exclusive of coal cleaned at central washeries operated by consumers; after 1926, when data became available on the tonnage cleaned by consumer-operated plants, the percentages include the total tons cleaned at the mines and at consumer-operated washeries.

[3] Data not available.

[4] One-half day or less.

TABLE 12.—*Salient trends in bituminous-coal and lignite mining industry in the United States, 1934–41*

	1934	1935	1936	1937	1938	1939	1940	1941
Production:								
Loaded at mine for shipment by rail.....net tons	313, 303, 729	319, 741, 376	370, 762, 901	[1] 399, 237, 575	295, 336, 027	331, 189, 620	380, 387, 674	425, 184, 319
Loaded at mine for shipment by water.....do	15, 127, 968	18, 327, 282	24, 867, 683	(1)	16, 902, 969	22, 229, 364	29, 493, 058	30, 240, 489
Shipped by truck or wagon.....do	18, 739, 320	21, 960, 252	27, 929, 298	[2] 37, 762, 612	25, 592, 058	29, 533, 824	35, 540, 476	40, 055, 638
Taken by locomotive tenders at tipple.....do	(3)	(3)	(3)	(2)	606, 857	826, 556	939, 058	1, 099, 582
Shipped by conveyor or tram to point of consumption.do	(3)	(3)	(3)	(2)	4, 221, 671	4, 317, 465	5 887, 994	6, 067, 697
Used by mine employees.....do	[3] 7, 374, 143	[3] 7, 773, 619	[3] 9, 571, 997	(2)	2, 032, 289	1, 901, 408	2, 035, 201	1, 872, 026
Used at mines for power and heat.....do	3, 175, 057	3, 102, 691	3, 227, 447	3, 052, 095	2, 493, 017	2, 565, 276	2, 442, 989	2, 488, 950
Made into beehive coke at mines.....do	1, 647, 805	1, 467, 902	2, 728, 577	4, 884, 054	1, 359, 876	2, 089, 475	4, 045, 050	7, 140, 544
Total production.....do	359, 368, 022	372, 373, 122	439, 087, 903	[4] 445, 531, 449	348, 544, 764	[5] 394, 855, 325	460, 771, 500	514, 149, 245
Number of active mines of commercial size:								
Class 1 (200,000 tons or more)	551	561	660	661	526	577	636	730
Class 2 (100,000 to 200,000 tons)	485	479	452	469	402	404	432	437
Class 3 (50,000 to 100,000 tons)	479	503	460	448	415	387	371	402
Class 4 (10,000 to 50,000 tons)	1, 072	1, 056	1, 085	1, 117	1, 042	1, 065	1, 157	1, 305
Class 5 (1,000 to 10,000 tons)	3, 671	3, 716	4, 218	3, 853	3, 392	3, 387	3, 728	3, 948
Total number over 1,000 tons	6, 258	6, 315	6, 875	6, 548	5, 777	5, 820	6, 324	6, 822
Average number of men employed at mines active:								
Underground	384, 947	389, 942	399, 367	(6)	370, 004	353, 476	365, 013	376, 765
Surface:								
In strip pits	7, 652	8, 533	8, 043	(6)	7, 877	8, 791	8, 983	10, 861
All others	65, 412	63, 928	69, 794	(6)	63, 452	59, 521	65, 079	69, 355
Total	458, 011	462, 403	477, 204	491, 864	441, 333	421, 788	439, 075	456, 981
Average number of days mines operated	178	179	199	193	162	178	202	216
Capacity of active mines with existing labor force:								
Per year of 308 days.....net tons	622, 000, 000	640, 000, 000	680, 000, 000	710, 000, 000	663, 000, 000	683, 000, 000	703, 000, 000	733, 000, 000
Per year of 280 days.....do	565, 000, 000	582, 000, 000	618, 000, 000	646, 000, 000	602, 000, 000	621, 000, 000	639, 000, 000	666, 000, 000
Per year of 261 days.....do	527, 000, 000	543, 000, 000	576, 000, 000	601, 000, 000	562, 000, 000	579, 000, 000	595, 000, 000	621, 000, 000
Output per man per day.....do	4. 40	4. 50	4. 62	4. 69	4. 89	5. 25	5. 19	5. 20
Output per man per year.....do	785	805	920	906	790	936	1, 049	1, 125
Underground output cut by machine.....do	284, 676, 715	293, 664, 208	348, 332, 330	(6)	278, 315, 365	313, 969, 394	369, 227, 277	408, 510, 296
Percent of underground output cut by machine	84. 1	84. 2	84. 8	(6)	87. 5	87. 9	88. 4	89. 0

Digitized by Google

[1] In 1937, coal loaded at mine for shipment by water is included with "loaded at mine for shipment by rail."
[2] In 1937, coal "taken by locomotive tenders at tipple," "shipped by conveyor or tram to point of consumption," and "used by mine employees" included with "shipped by truck or wagon."
[3] In 1934, 1935, and 1936, data were not collected in such form as to permit a separation of coal "taken by locomotive tenders at tipple," "shipped by conveyor or tram to point of consumption," and "used by mine employees." They are all included here under "used by mine employees."
[4] Total production differs from sum of items shown by amount of changes in inventory and tonnage not accounted for in distribution analysis. This tonnage amounted to 895,113 net tons.
[5] Includes 202,337 tons of coal reported as net changes in stocks at mines, January 1, 1939, to January 1, 1940.
[6] Data not available.
[7] Includes central washeries operated by consumers.

Wyoming	6,315,262	201,534	36,354	93,180	6,646,330	2.09	3,407	56	847	4,310	203	874,568	7.60
Total United States	455,424,808	40,055,638	9,039,305	[3] 9,629,494	514,149,245	2.19	376,765	10,861	69,355	456,981	216	98,902,253	5.20

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water.

[2] Includes coal transported from mines to points of use by conveyor, chute, or aerial tramway.

[3] Includes coal made into beehive coke at mines in the following States: Alabama, 4,830 tons; Colorado, 124,198 tons; Kentucky, 3,424 tons; Pennsylvania, 6,037,747 tons; Tennessee, 11,920 tons; Utah, 20,106 tons; Virginia, 525,067 tons; and West Virginia, 413,252 tons; a grand total of 7,140,544 tons.

[4] Value received or charged for coal f. o. b. the mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by the producer at average prices that might have been received if such coal had been sold commercially.)

[5] Since it is necessary to conceal certain items in the lignite break-down of disposition of coal, the figures are included here in the column where the greater part of the concealed tonnage would appear.

[1] Figures represent output and number of working days in that part of the week included in the calendar year shown. Total production for the week of January 4, 1941, was 8,994,000 net tons and for January 3, 1942, was 10,104,000 net tons.

[2] Average daily production for the entire week and not for the working days in the calendar year shown.

Digitized by Google

TABLE 16.—*Final coal production in the United States, by States, with estimates by months, in thousands of net tons, in 1941*

[The toals for the year are based upon final complete returns to the Bituminous Coal Division from all operators known to have produced more than 1,000 tons a year. The apportionment of the known yearly total among the 12 months is based upon the best information available—in some States upon direct tonnage reports by operators to the State mine department, in most cases upon current records of railway carloadings and waterway shipments]

AVERAGE VALUE

Before the Bituminous Coal Act of 1937 was passed, the most valuable single index of the trend of prices at the mines was the "average value per ton, f. o. b. mines," as given in the familiar annual coal reports of the Bureau of Mines, United States Department of the Interior. This series was referred to in Bureau of Mines reports as representing "bituminous coal," and it covered all coal (other than Pennsylvania anthracite) produced in the United States. It represented the bituminous-coal industry as the term ordinarily was used in the trade and included the lignite of the Dakotas, Texas, and Montana, as well as any small tonnages of hard coal produced outside of Pennsylvania.

With the passage of the Coal Act, the Bureau of Mines relinquished the collection of statistics relating to bituminous coal, effective June 30, 1937, though continuing to compile data regarding lignite and Pennsylvania anthracite. Effective the same date, the Coal Commission became responsible for the compilation of data on bituminous coal, though not attempting to collect data regarding lignite, which was specifically exempted by the act. The records of the Commission (now Bituminous Coal Division, United States Department of the Interior) relate to all coal other than Pennsylvania anthracite, Virginia semianthracite, and lignite.

To permit comparison of the old and new series, therefore, it is necessary to separate the lignites from the bituminous coals, though for the convenience of the student the combined average for the two is continued in a form as nearly comparable as possible to the old series. (See table 18.)

A more important change in the two series relates to the treatment of selling expenses. The old Bureau of Mines series of "value at the mines" excluded the selling cost. Reporting operators were asked to state the "Amount received at the mines f. o. b. cars less the selling expense." No details were asked regarding the items included in the value, and no systematic effort was made to follow up the exclusion of selling expenses. It was realized at the time that some producers might find it impractical to exclude selling costs and that some part of the selling expenses of the industry might be included in the results. Nevertheless, the reports were checked for consistency from year to year, the questions were retained in the same form without change, and the results are believed to have been comparable from one year to the next. The new series of the Coal Commission represents the total or gross realization on all coal produced and specifically includes the selling cost.

The two sets of data may not be precisely comparable with respect to coal produced but not sold on the commercial market. In the Bureau of Mines series reporting operators were instructed that the "value of coal not sold but used by producer, also mine fuel and coal made into coke should be estimated at average prices that might have been received." The instructions of the Coal Commission regarding such items were in effect similar, though given in greater detail.

A comparison of the two series is possible for 1936. In that year the average value per ton on the old (Bureau of Mines) basis amounted to $1.761 per ton for bituminous coal, excluding lignite. The aver-

Digitized by Google

age gross realization, according to data collected by the Coal Commission, was $1.831 per ton. The difference amounts to $0.07 per ton—an amount somewhat less than the average selling expenditure computed per ton of all coal produced, as reported to the Coal Commission. The comparison confirms previous indications that the great majority of operators reporting in earlier years had followed instructions and omitted selling expenses in computing the average value but that some of them had included the selling expense. The change in method of reporting should be kept in mind in comparing the two sets of data. As the reports to the Commission were submitted on a detailed accounting return and made under oath they are to be accepted. The returns of earlier years, upon a voluntary basis and not in all instances uniform as to treatment of selling costs, seem to have been thoroughly comparable from one year to the next and afford the best available index to the rise and fall of the mine prices received by operators down to 1936.

TABLE 18.—*Trend of average value in the United States of bituminous coal and lignite per ton, f. o. b. mines, 1929–41*

Year	Bituminous coal (subject to regulation under 1937 act) [1]	Lignite [2]	Total
Average value per ton less selling cost (Bureau of Mines series):			
1929	$1.782	$1.548	$1.781
1930	1.702	1.556	1.701
1931	1.542	1.410	1.541
1932	1.313	1.313	1.313
1933	1.337	1.188	1.336
1934	1.751	1.387	1.749
1935	1.772	1.120	1.767
1936	1.761	1.061	1.756
Average gross realization, including selling cost (Bituminous Coal Division series):			
1936	1.831	[3] 1.061	1.826
1937	1.946	[3] 1.080	1.939
1938	1.955	[3] 1.071	1.947
1939 [4]	1.850	1.158	1.845
1940	1.913	[3] 1.156	1.908
1941	2.194	[3] 1.237	2.189

[1] Includes all coal produced other than Pennsylvania anthracite and the lignite included in the second column.
[2] North Dakota, South Dakota, and the lignite counties of Montana and Texas.
[3] Figures from the Bureau of Mines. Data on sales realization were not collected from lignite mines by the Bituminous Coal Division. Figures for 1936-38 and 1940 exclude selling cost as before. Figure for 1941 includes selling cost.
[4] Producers were asked to exclude selling cost in reporting value, but a number of them included such costs.

LABOR STATISTICS

Men employed.—An average of 456,981 men was employed at bituminous-coal mines in 1941, a 4.1-percent increase over the total of 439,075 for 1940 (see fig. 8). Statistics on men employed in 1941 represent annual averages of the number of workers on the rolls on the days when the mines were in operation.

The method used here in calculating employment gives an accurate measure of the working force in the coal industry, but it does not consider the time lost by men on the rolls through intermittent operations. To measure the influence of intermittency upon employment the factor of mine activity as indicated by the average number of days of

Digitized by Google

plant operation was recorded separately. The average number of men employed when the mines were in operation was then used, in conjunction with the average number of days of operation, as a measure of the total volume of employment in the industry.

Days operated.—The average number of days of operation at bituminous-coal mines in 1941 was 216. This represents an increase over the average of 202 days for 1940. All statistics on days of mine operation included in this report are weighted averages, in which the operating time of each mine has been weighted by the number of its employees. Several coal-mining States publish series on the number of days worked that are simple averages of the figures for each reporting mine, regardless of size. As these unweighted averages are likely to be unduly depressed by small mines, which generally operate fewer days than the larger ones, they tend to understate the working time of a typical mine employee.

Man-days of labor.—Only a small proportion of the bituminous-coal-mine operations, however, keep an accurate record of man-days or man-hours worked. Consequently, man-days have been computed by multiplying the number of workers employed by the number of operating days. Although these computations were made for each individual mine, the combined total is necessarily only an approximation.

Until the American coal industry arranges to keep an accurate record of man-days or man-hours of employment all computations of accident rates, daily earnings, and output per man will remain subject to qualification. Meanwhile, the method of multiplying men by days must be accepted as the best available procedure.

Data for 1941 indicate that bituminous-coal-mine employees performed 98,902,253 man-days of labor during the year. Table 14 gives a summary record of men employed, days operated, and output per man per day at bituminous-coal mines, by States, in 1941. Details by counties for 1941 are shown in table 40.

Length of working day.—Table 19 summarizes the replies of mine operators to the question, "Number of hours operated per shift."

The reports of more than 7 hours of work per shift in 1941 consist partly of (1) work for which the operator has included time when the men are entering or leaving the mine, (2) work for which the operator has reported the time of certain employees who work longer than other employees, as in stripping overburden, or (3) operations where work is staggered and two crews of men overlap. There were, however, a number of mines in 1941 where the established day was 8 hours. As shown by the table, most of these were very small. Numerous mines, especially the smaller ones, failed to answer the question.

It was found that 92.6 percent of the men employed were in 7-hour mines and that the weighted average working shift was 7.03 hours.

The established working day does not of itself measure the length of time that men actually work or the time that they are underground, because of the possibility of overtime, because the mine may sometimes shut down before the full day is over, because the miner may go home before the mine stops, and because he spends a considerable time going to and from his place of work underground.

As interpreted in the wage agreements, the 7-hour day means 7 hours of labor at the usual working place, exclusive of any time for

Digitized by Google

lunch and exclusive of the time spent in going from the entrance of the mine to the working place and back again. As noted, these figures represent the operator's statement of the nominal operating day for the mine. They do not purport to represent the time actually worked by the men. On the one hand, they make no allowance for tonnage or piece workers who leave early; on the other hand, they make no allowance for tonnage men who continue at work after the mine as a whole is shut down, or who go into the mine to work on days when the tipple is idle.

TABLE 21.—*Bituminous coal and lignite loaded for shipment by railroads and waterways in the United States, as reported by mine operators, in net tons, in 1941*—Continued

Route	State	1941	
		By State	Total for route
WATERWAYS			
Allegheny River	Pennsylvania	1,048,724	1,048,724
Black Warrior River	Alabama	195,480	195,480
Illinois River	Illinois	489,375	489,375
Kanawha River	West Virginia	2,127,532	2,127,532
Monongahela River	Pennsylvania	24,490,010	24,732,051
	West Virginia	242,041	
Muskingum River	Ohio	934,094	934,094
Ohio River	Kentucky	219,836	689,543
	Ohio	54,886	
	Pennsylvania	1,869	
	West Virginia	412,952	
Youghiogheny River	Pennsylvania	23,690	23,690
Total waterway shipments		30,240,489	30,240,489
Total loaded at mines for shipment by railroads and waterways,		455,424,808	455,424,808
Shipped by truck or wagon		40,055,638	40,055,638
Taken by locomotive tenders at tipple		1,099,582	1,099,582
Shipped by conveyor belt or tram to point of consumption.		6,067,697	6,067,697
Coal used by employees		1,872,026	1,872,026
Used at mine for power and heat		2,488,950	2,488,950
Made into beehive coke at mine		7,140,544	7,140,544
Total production		514,149,245	514,149,245

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water. In general, the figures show the quantity of bituminous coal and lignite originated for each railroad and waterway, as reported by the mine operators. It must be noted that in 1 year an operator may report coal loaded on the subsidiary railroad and in another year the same operator may report coal loaded on the parent railroad system.

[2] Texas lignite mines shipping over the Missouri-Kansas-Texas, Rockdale, Sandow & Southern, St. Louis Southwestern of Texas, and the Texas Short Line have been included with the International-Great Northern.

STRIPPING OPERATIONS

TABLE 24.—*Stripping operations of all types in the bituminous-coal and lignite fields of the United States, by States and counties, in 1941*

[Returns for mines that recover coal both by stripping and by underground operations do not permit separating men engaged in stripping from those engaged in other work. For this reason, the figures of men employed represent all persons working at these mines, including those underground. The total tons produced by both methods at these mines are also shown]

State and county	Number of strip pits	Number of power shovels			Coal produced (net tons)		Average number of employees				Average number of days mines were active	Number of man-days worked	Average tons per man per day
		Steam	Electric	All others	Mined by stripping	Total at same mines	Underground	Surface		Total

MECHANICAL LOADING IN UNDERGROUND BITUMINOUS-COAL AND LIGNITE MINES

Mechanical loading devices used in underground bituminous-coal and lignite mines are divided into two general classes: Those that practically eliminate hand-shoveling, which are known as mobile loaders, scrapers, and self-loading conveyors or duckbills; and those that greatly reduce the labor of hand-shoveling, which are known as hand-loaded face conveyors and pit-car loaders.

The first systematic record of mechanical loading began in 1923 when 60 mines loaded 1,879,726 net tons (0.3 percent of the underground output) with the aid of mechanical loading devices. Ten years later (in 1933) mechanical loading had spread to 283 mines, and 37,820,461 net tons (12 percent of the total underground output) were loaded mechanically. Since 1933 the proportion mechanically loaded has increased each year and in 1941 it amounted to 41 percent of the total underground bituminous coal and lignite mined in the United States.

During the 3 years 1939–41 the percentage loaded by each class has been fairly constant, the mobile loaders, scrapers, and duckbills handling about 76 percent and the hand-loaded conveyors and pit-car loaders about 24 percent of the total.

Detailed statistics on mechanical loading given in the following tables (27 to 33, inclusive) pertain to underground coal mines and do not include strip mines or equipment used for handling coal on the surface. All tonnage figures on coal mechanically loaded include the initial phase of loading only; for instance, if conveyors were used in conjunction with mobile loaders, the tonnage is shown under mobile loading machines and not under conveyors.

Sales of mechanical loading equipment in 1942.—The estimated capacity of mechanical loading equipment sold for underground use in all coal mines was 7.7 percent less in 1942 than in 1941. This decrease was due in part to some of the manufacturers devoting a portion of their facilities to war work. Table 27 shows the sales reported, by type of equipment, and the number of manufacturers reporting for 1935–42.

Sales of conveyors to bituminous-coal and lignite mines in 1942 totaled 1,167 units. This figure excludes duckbills, which have been included in all previous years. Therefore, the figures for 1942 are not comparable with those for 1941 or earlier years. By excluding sales of duckbills, some of the overlapping sales of conveyors are eliminated. For instance, in 1940 there were 2,919 conveyors, including those hand-loaded and those equipped with duckbills, in active use at bituminous-coal and lignite mines, as reported by mine operators. By adding 1940 conveyor and duckbill sales of 1,573 units, 4,492 units appeared available for use in 1941, whereas the actual number reported in use by mine operators was 3,595, or 897 less. This difference represents idle or worn-out and obsolete equipment, duplications in reporting sales, and a small number of conveyors used in conjunction with mobile loaders.

The number of mobile loaders, scrapers, and conveyors shipped into the various States and groups of States in 1942 and the number

Digitized by Google

of units in actual use in 1941 are shown in table 29. Pennsylvania bituminous-coal mines received the largest number of mobile loaders sold in 1942; West Virginia was in second place, and Alabama and Kentucky tied for third place.

All of the 15 scraper units sold in 1942 went to the bituminous-coal mines.

Conveyor sales in 1942, in relation to the number in actual use in 1941, were greater in the Middle Western States than in any other regions.

Detailed statistics of mechanical loading in bituminous-coal and lignite mines in 1940 and 1941, by types of equipment.—During 1941, the latest year for which records are available, the approximate percentage of the tonnage loaded by each type of equipment was as follows: Mobile loaders, 68; hand-loaded conveyors, 21; duckbills, 8; pit-car loaders, 2; and scrapers, 1.

Mobile loaders have handled more coal than any other type of mechanical loading device, and since 1934 they have loaded more than all the other types together. The most common method of employing mobile loaders is for loading coal directly into mine cars, but they also load into shuttle cars (rubber-tired trackless haulage units) and onto conveyors. During 1941, 86 percent of the bituminous coal and lignite handled by mobile loaders was loaded directly into mine cars, 11 percent into shuttle cars, and 3 percent onto conveyors.

In the underground bituminous-coal and lignite mines, 1,985 mobile loaders handled 126,478,074 net tons in 1941, an average of 63,717 tons per mobile loader per year; hand-loaded face conveyors averaged 14,440; duckbills, 18,932; pit-car loaders, 5,679; and scrapers, 11,832 per year per unit for the same period (see tables 30 and 31).

Mechanical loading, by States.—Illinois led all other States in underground tonnage mechanically loaded from 1928 to 1938; then it was passed by West Virginia in 1939. In 1941, West Virginia produced 57,511,968 net tons of mechanically loaded coal, followed by Pennsylvania with 35,164,964 net tons, Illinois with 33,273,976, Ohio with 11,943,605, and Kentucky with 11,496,678. These five States produced 80 percent of the total output of mechanically loaded bituminous coal in the United States in 1941.

Detailed data, by States, on number of mines and machines and production of mechanically loaded coal compared with total production at mines using mechanical loading devices are given in table 31. Comparative changes in underground mechanical loading in 1940–41, by States, are shown in table 32.

Table 33 gives bituminous coal and lignite mined by stripping compared with underground hand-loaded and machine-loaded tonnage, by States, for 1941.

[1] Includes those mines in which all of the tonnage mechanically loaded was obtained with machines that substantially eliminate hand shoveling; that is, mobile loaders, scrapers, and conveyors equipped with duckbills and other self-loading heads. Some mines in this class also use conveyors in conjunction with mobile loaders to perform the initial phase of transportation.

[2] Includes those mines in which all the tonnage mechanically loaded was obtained with hand-loaded conveyors and pit-car loaders.

[3] Number of units.

[4] Included under "Undistributed" to avoid disclosing individual operations.

[2] Includes Alaska, Arizona, Georgia, Idaho, and Oregon.

MECHANICAL CLEANING

Complete annual data on the mechanical cleaning of bituminous coal in the United States were first gathered for 1927; during that year 5.3 percent of the total production was cleaned by wet or pneumatic methods. This percentage increased annually, and in 1941 amounted to 23 percent or 117,469,857 net tons of clean coal. Tables 34, 35, 37, and 38 include data on all coal mined in the United States (excluding Alaska) except Pennsylvania anthracite. Tables 36 and 39 are upon the same basis but do not include consumer-operated plants. There are no mechanical cleaning plants at lignite mines.

For purposes of comparison, data on Alaska, which had one wet-washing installation, have not been included in the following tables. This one plant produced 52,754, 64,567, and 69,665 net tons of cleaned coal in 1939, 1940, and 1941, respectively.

Consumer-operated plants include plants owned by steel companies which receive coal from various mines (but usually from affiliated companies), clean it, and then consume it directly at the plant.

Table 34 compares bituminous coal cleaned in 1940 and 1941, by method of cleaning. Both wet and pneumatic methods increased in 1941 over 1940.

Mechanical cleaning, by types of equipment.—The tonnage of bituminous coal cleaned by wet-washing methods reached 100,307,969 net tons in 1941—an increase of 15 percent over 1940. The quantity

Digitized by Google

cleaned by pneumatic methods was 17,161,888 net tons—also a 15-percent increase over 1940.

Table 35 compares the number of cleaning plants and the net tons of cleaned coal, by types of equipment, for 1940 and 1941. During 1941, 380 wet-washing and 80 pneumatic cleaning plants were in operation. Forty-four tipples used both wet and dry methods at the same plant; deducting these duplications gives a net total of 416 plants that cleaned coal in 1941 compared with 386 in 1940.

Wet methods of cleaning coal include piston- or common-type jigs, Baum-type jigs, concentrating tables, launders and upward-current classifiers, and combinations of jigs with concentrating tables and jigs with launders or upward-current classifiers. Baum-type jigs cleaned approximately 40 percent of the coal cleaned by wet methods during 1941.

Pneumatic methods of coal cleaning include air tables, air flow, air sand, and any combinations of these three methods. During 1941, air tables cleaned over 50 percent of the coal cleaned by pneumatic methods.

Table 36 lists the total production in 1940 and 1941 at bituminous-coal mines that have cleaning plants, by types of equipment. This table shows that 185,398,504 net tons were produced at mines with cleaning plants in 1941, but the cleaned coal obtained at these mines totaled 108,218,314 net tons (see table 38) or 58 percent of the total produced. The remainder of the output (42 percent) presumably represents the larger sizes, which are generally hand-picked.

Coal cleaning, by States.—In volume of total tonnage of bituminous coal mechanically cleaned in 1941, Pennsylvania led; West Virginia, Illinois, Alabama, and Indiana followed in the order named. These five States supplied 98,839,286 tons (84 percent) of the total. Table 37 shows the number of plants in operation, net tons of clean coal, and percentage of State output mechanically cleaned in 1940 and 1941.

Results of operations and the relation between raw coal, clean coal, and refuse at bituminous-coal-cleaning plants by States in 1941 are shown in table 38.

Methods of mining at mines served by cleaning plants.—Mechanical loading, both in underground mines and strip pits, appears to be closely related to mechanical cleaning. Table 39 shows the mining methods at mines that have cleaning plants. Production of coal from strip mines in 1941 was 55,071,609 tons (see table 33); 24,773,543 tons (45 percent) came from strip mines having mechanical cleaning tipples. There were 186,667,250 tons of underground coal loaded mechanically in 1941, of which 93,373,789 tons (50 percent) passed through tipples equipped with mechanical cleaning devices. Hand-loaded underground coal production in 1941 totaled 272,410,386 tons, of which 25 percent passed through tipples equipped with cleaning plants.

TABLE 39.—*Method of mining at bituminous-coal mines in the United States served by cleaning plants, 1939–41* [1]

[Does not include any estimate for mines that may ship to consumer-operated plants]

Method of mining in use	Total production from mines that move coal to cleaning plants (net tons) [2]			Change, 1941 from 1940 (percent)
	1939	1940	1941	
Mined from strip pits	17,960,049	20,029,770	24,773,543	+23.7
Mechanically loaded underground	53,495,851	66,148,465	93,373,789	+41.2
Hand-loaded underground	61,805,096	75,493,332	67,251,172	−10.9
Total	133,260,996	161,671,567	185,398,504	+14.7

[1] Excludes Alaska.
[2] Based upon shipping weights and includes some marketable coal that did not pass through cleaning plants.

DETAILED STATISTICS, BY STATES AND COUNTIES

Detailed production and employment statistics are given in table 40 for each coal-producing county in the United States from which three or more operators submitted reports for 1941. Statistics on counties with less than three reporting producers have been combined with data for other counties in the same State to avoid disclosing individual returns, unless permission to publish has been granted by the operators. Production of mines on the border between two States has been credited to the State from which the coal is extracted rather than that in which the tipple is situated. If the coal is mined from lands in both States, the tonnage has been apportioned accordingly.

In this series the reported production is classified according to the principal methods of distribution or use. Beginning with 1932, the series was expanded to include data on the growing volume of coal moving from mine to consumer by truck. For 1933–36 this tonnage was shown as "commercial sales by truck or wagon." In 1937 this tonnage was shown as "truck deliveries, including local sales." (See Minerals Yearbook, 1939, p. 813.) In 1938 the truck tonnage was shown as "shipped by truck or wagon." The truck figures for 1933 to 1936, inclusive, and 1938 to 1941, inclusive, are reasonably comparable.

The data in this report, like those published for many years by the Bureau of Mines, relate only to mines with an annual output of 1,000 tons or more. Although all mines, regardless of size, are subject to regulation under the provisions of the National Bituminous Coal Act of 1937, it seemed advisable to maintain the continuity of the old series by excluding the very small mines that sell by truck or wagon. This fact should be borne in mind when the statistics in this report are compared with similar data compiled by State mine departments. Differences arise largely from variations in coverage of the State reports, some of which include data for all mines, regardless of size, and others only data for mines employing more than a specified minimum number, which ranges from 2 to 10 men.

Because of a change in the method of reporting, the statistics of average production per man per day for 1932 to 1936 and 1938 to 1941 are not precisely comparable with those for earlier years. Before 1932 they were based upon the calculated number of man-shifts, obtained by multiplying the average number of men employed at each mine by the number of days worked at the mine. Since 1932

Digitized by Google

operators have been asked to make a special report of the number of man-shifts actually worked, if possible. The number of operators able to furnish this information has been small, although it is increasing from year to year. These reports were utilized to improve the accuracy of the record. Otherwise, the man-shifts were calculated by multiplying the number employed underground and on the surface by the number of days worked by the mine and tipple, respectively.

TABLE 40.—*Production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States in 1941*—Continued

[Exclusive of mines producing less than 1,000 tons]

County	Disposition of coal produced (net tons)					Average value per ton [3]	Average number of employees				Average number of days mines were active	Number of man-days worked	Average tons per man per day
	Loaded for shipment by rail or water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Used by mine employees, taken by locomotive tenders at tipple, or other uses at mine [2]	Used at mine for power and heat or made into beehive coke at mine	Total quantity		Underground	Surface		Total			
								In strip pits	All others

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water.

[2] Includes coal transported from mines to points of use by conveyor, chute, or aerial tramway.

[3] Value received or charged for coal f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[4] Includes 4,830 tons made into beehive coke at mines in Jefferson County, Ala., in 1941.

[5] No coal was made into beehive coke at mines in 1941.

[6] Includes 124,198 tons made into beehive coke at mines in Las Animas County, Colo., in 1941.

[7] "Other counties" in Illinois include Bond, Crawford, Greene, Hancock, Jefferson, Logan, McDonough, Macon, Marion, Marshall, Montgomery, Tazewell, Wabash, Warren, Will, and Woodford.

[8] Much of the output is obtained from strip pits or by use of loading machines, in which types of operations production per man per day is large.

[9] Production of Home Riverside and Alston mines is credited to Missouri, and production of Hume-Sinclair (Tiger mine) is credited to Kansas.

[10] Output obtained chiefly from strip pits, in which production per man per day is large.

Digitized by Google

[11] Includes 3,424 tons made into beehive coke at mines in Jackson County, Ky., in 1941.
[12] "Other counties" in Eastern Kentucky include Elliott, Leslie, McCreary, Madison, Magoffin, Morgan, and Owsley.
[13] "Other counties" in Missouri include Cedar, Chariton, Clark, Dade, Daviess, Grundy, Howard, Jasper, Johnson, Lincoln, Moniteau, Monroe, and Morgan.
[14] "Other counties" in Montana bituminous coal include Blaine, Fergus, Flathead, Gallatin, Judith Basin, Park, Phillips, and Pondera.
[15] In North Dakota some lignite "made into briquets" is included with "Other uses at mine." In South Dakota a small amount of colliery fuel is included with "Other uses." In Texas a small amount of colliery fuel is included with "Shipped by truck or wagon."
[16] Includes coal made into beehive coke at mines in the following counties in Pennsylvania in 1941: Cambria, 109,623 tons; Fayette, 4,371,446 tons; Greene, 7,635 tons; Indiana, 305,201 tons; and Westmoreland, 1,243,842 tons—a grand total of 6,037,747 tons.
[17] Includes 11,920 tons made into beehive coke at mines in Grundy County, Tenn., in 1941.
[18] Includes 20,106 tons made into beehive coke at mines in Carbon County, Utah, in 1941.
[19] Includes 525,067 tons made into beehive coke at mines in Wise County, Va., in 1941.
[20] Includes coal made into beehive coke at mines in the following counties in West Virginia in 1941: Fayette, 347,934 tons; Preston, 65,318 tons—a grand total of 413,252 tons.

STATISTICS ON LIGNITE IN 1941[2]

PRODUCTION

The statistics in this chapter on the lignite industry in the United States were compiled by the Bureau of Mines from annual reports received from producers of lignite in the areas mapped as lignite in Geological Survey Professional Paper 100-A, The Coal Fields of the United States. Subbituminous coal, sometimes called black lignite, is not included in these statistics.

The production of lignite continued to decline in 1941, amounting to 2,775,832 net tons compared with 2,939,201 tons in 1940 and 3,042,537 tons in 1939. These figures do not include the output from some mines producing less than 1,000 net tons annually. The average value per net ton was $1.24 in 1941, an increase from $1.16 per ton in 1940. The number of employees in 1941 totaled 1,644, compared with 2,070 in 1940; and the average output per man per day, based upon calculated man-days, was 9.54 net tons, ranging from a low of 3.44 tons in Montana to a high of 10.23 tons in North Dakota. The industry worked an average of 177 days in 1941 and 178 days in 1940. The length of the working day in most of the mines was 8 hours, although some mines reported a 7-hour day to the Bureau, and a few, a 9-hour day.

North Dakota produced 83 percent of the total United States output of lignite in 1941; Texas followed with 12 percent, and the output of South Dakota and Montana taken together totaled 5 percent. In 1940 the North Dakota production represented 75 percent of the total, that of Texas 21 percent, and South Dakota and Montana combined 4 percent.

For 1941 the Bureau of Mines received reports from 195 lignite mines. Of the total output of the industry, 6 mines, producing 200,000 to 500,000 net tons each, supplied 62 percent; 1 mine reporting production of 100,000 to 200,000 tons, 6 percent; 5 with an output of 50,000 to 100,000 tons each, 13 percent; 12 in the 10,000- to 50,000-ton class, 8 percent; and 171 mines producing less than 10,000 tons each, 11 percent. North Dakota, with 155, had the greatest number of mines. Montana was next, with 20 mines, and South Dakota and Texas followed, with 14 and 6, respectively.

Strip-pit operations were the source of 60 percent of the total production of lignite in 1941, whereas only 13 percent of the total Pennsylvania anthracite production was mined by this method and about 10 percent of the bituminous-coal output was recovered from strip pits.

According to the Federal Power Commission, 842,250 net tons of lignite were used in 1941 for generating electric energy in the United States; this tonnage was equivalent to 30 percent of the total 1941 production. The consumption in the West North Central Division was 583,954 tons, and the West South Central and Mountain Divisions consumed 250,262 and 8,034 tons, respectively.

The following tables contain detailed statistics for lignite in 1941. Statistics of the lignite industry in 1942 were not available for inclusion in this chapter but may be obtained in mimeographed form upon request to the Coal Economics Division of the Bureau of Mines.

[2] Compiled by J. A. Corgan and A. V. Coleman, Coal Economics Division, Bureau of Mines.

Total	337,326	284	.84	202	36,301	180	9.29

[1] Based upon "calculated" man-days.
[2] Output is obtained chiefly from strip pits, in which production per man per day is large.

NUMBER AND SIZE OF MINES

TABLE 43.—*Number and production of lignite mines in the United States, in 1941, classified by size of output*

Class	Mines		Production		
	Number	Percent	Total (net tons)	Average per mine (net tons)	Percent
1 (200,000–500,000 tons)	6	3.1	1,710,669	285,112	61.6
2 (100,000–200,000 tons)	1	.5	177,624	177,624	6.4
3 (50,000–100,000 tons)	5	2.6	358,414	71,683	12.9
4 (10,000–50,000 tons)	12	6.1	219,442	18,287	7.9
5 (Under 10,000 tons)	171	87.7	309,683	1,811	11.2
Total	195	100.0	2,775,832	14,235	100.0

METHODS OF RECOVERY

TABLE 44.—*Lignite mined by different methods in the United States in 1941, by States, in net tons*

State	Mined by hand	Shot off the solid	Cut by machines [1]	From strip pits	Total
Montana	[2] 14,818	[2] 291,195	13,434	[2] 76,672	58,793
North Dakota	7,161	188,754	585,829	1,527,144	2,308,888
South Dakota	150	4,245	.....	66,430	70,825
Texas	(3)	(3)	.....	(3)	337,326
Total	22,129	484,194	599,263	1,670,246	2,775,832

[1] A total of 20 machines was used—11 "permissible" and 9 of other types.
[2] Montana includes Texas.

STRIPPING OPERATIONS

The output of lignite from strip pits in 1941 amounted to 1,670,246 tons, compared with 1,512,308 tons in 1940. Lignite produced by this method of mining represented 60 percent of the total output of the industry in 1941 and 51 percent in 1940. As for many years in the

Digitized by Google

past, the largest producer of lignite from strip pits was North Dakota, whose output in 1941 was 1,527,144 tons compared with a combined total of 143,102 tons from Texas, Montana, and South Dakota.

Detailed statistics for stripping operations in the lignite industry in 1941 are given in table 45.

TABLE 45.—*Summary of stripping operations that produced lignite in the United States in 1941, by States*

State	Number of strip pits [1]	Number of shovels, dragline excavators, and coal-loading machines [2]	Coal mined by stripping (net tons)	Total value at mines (thousand dollars)	Average value per ton	Number of employees			Average number of days mines operated	Man-days of labor [3]	Average tons per man per day [3]
						In strip pits	All others	Total			
Montana and Texas	4	7	76,672	41	$0.53	38	1	39	73	2,847	26.93
North Dakota	67	46	1,527,144	1,898	1.24	444	92	536	175	93,878	16.27
South Dakota	8	7	66,430	101	1.52	44	7	51	195	9,962	6.67
Total	79	60	1,670,246	2,040	1.22	526	100	626	170	106,687	15.66

[1] Includes some pits in which the stripping is done by hand.
[2] In some cases the same equipment was used for stripping or excavating and for loading the coal; this duplication has been eliminated. In some cases the coal was excavated by machine and loaded by hand.
[3] Based upon calculated man-days.

REVIEW OF 1942

The accelerated demand for Pennsylvania anthracite in 1942 was created largely by the shortages of fuel oil and coke in the New England and Middle Atlantic States, and by increased industrial activity, expanded purchasing power, and rising exports, particularly to Canadian markets. The output of 60,328,000 net tons in 1942 was the largest since 1930 and represented an increase of 7 percent over the production of 56,368,000 tons in 1941; despite the increase of about 4,000,000 tons, the output was not sufficient to meet the demand for anthracite. In 1942 the contract between the producers and the United Mine Workers of America permitted the industry to work 40 weeks of 5 days each and 12 weeks of 6 days each. In January 1943 a 6-day week was inaugurated, and this increased working time should tend to alleviate somewhat the manpower shortage that existed in 1942; thus, should the demand for anthracite continue at the same level, the industry will be in a better position regarding working time than in 1942.

The Bureau of Mines cooperated closely with the Office of Solid Fuels Coordination for War in handling problems relating to production, consumption, distribution, utilization, and transportation of anthracite, bituminous coal, and coke.

Funds for research pertaining to the Pennsylvania anthracite industry's problems, to be expended at the direction of the Secretary of the Interior acting through the Bureau of Mines, were authorized in

Digitized by Google

December 1942 by the Congress, but no appropriation for the work has yet been made available.

The Federal Anthracite Coal Commission, created by House Joint Resolution 255 to investigate economic conditions in the anthracite-producing areas of the United States, submitted its report to the President and the Congress in April 1942. The report recommended measures for both short-term and long-term improvements which are discussed elsewhere in this chapter.

The Anthracite Commission continued its functions relating to the production of anthracite, and through its efforts arrangements were made for legitimate companies to purchase "bootleg" coal lawfully and to employ men formerly working in illicit operations.

Anthracite Industries, Inc., financially supported by producers representing more than 80 percent of the anthracite output, is working on the most extensive research program ever undertaken by the anthracite industry.

The Anthracite Tidewater Emergency Bureau, a voluntary organization representing anthracite producers, wholesalers, and railroads delivering at tidwater points, was established at the suggestion of the Interstate Commerce Commission and the Car Service Division of the American Association of Railroads to expedite rapid turn-around movement of railroad cars at terminal piers. This newly formed Bureau compiles statistics concerning cars of coal standing at tidewater piers and endeavors to prevent undue detention of such cars, thereby assisting the railroads in meeting the increased demands for transportation due to the war. It is thought that the Bureau will bring about more efficient utilization of railroad equipment, boats, and barges at a time when full use of this equipment is urgently needed.

The failure of the anthracite operators and miners to agree upon terms of a new contract to supersede the agreement that expired on April 30, 1943, was followed by several stoppages of work and the loss of considerable tonnage. These developments and the bitter controversies arising therefrom received widespread attention, and the public has been fully advised of them by press and radio. They will be detailed for the record in the 1943 edition of this chapter.

Definition of Pennsylvania anthracite.—Pennsylvania anthracite includes all nonbituminous coal mined in that State, and for historical purposes data on the output of the Bernice Basin in Sullivan County are included in this chapter, although the coal of this basin has been officially classified as semianthracite. The anthracite fields are in the northeastern part of the State, and the coal is mined in the following counties: Carbon, Columbia, Dauphin, Lebanon, Lackawanna, Luzerne, Northumberland, Schuylkill, Susquehanna, and Wayne.

Statistical trends.—Tables 1 and 2 present pertinent statistical data on the Pennsylvania anthracite industry.

The war and anthracite.—Anthracite has contributed to the physical well-being of millions of people who live in the highly populated and industrialized New England and Middle Atlantic States (a large number being employed in vital war industries) and who depend entirely on anthracite for warmth and comfort in the home. In addition to supplying the fuel requirements of those normally using anthracite, the industry was called upon to increase its output substantially to provide heat for thousands of people who had used fuel oil and coke before the war but who were unable to obtain their normal supply on account of shortages resulting from difficulties incurred in transporting oil and the withdrawal of coke from the domestic market because of metallurgical demands. In addition to its use in heating homes, apartments, hotels, hospitals, and public buildings, anthracite is used by railroads, public utilities, and industrial plants; and Army camps are now using substantial quantities for space heating and cooking.

Anthracite aided the war effort not only in the United States but also in Canada, where shortages of gas and oil required increased use of coal. Exports, virtually all of which went to Canada, increased from 2,668,000 net tons in 1940 to 3,380,000 tons in 1941 and totaled 4,439,000 tons in 1942. About 90 percent of the exported coal was Pea and larger; these sizes are used for comfort heating.

In November 1941 the President by letter requested the Secretary of the Interior to act as Solid Fuels Coordinator for National Defense to handle problems relating to the production, distribution, consumption, and utilization of both anthracite and bituminous coal. Pursuant to this request the Office of Solid Fuels Coordinator for National Defense was established in the Department of the Interior to provide the machinery for carrying out the President's directions. The name of the Office was changed to the Office of Solid Fuels Coordinator for War by direction of the President in May 1942, and in April 1943 the President, in an executive order, abolished the Coordinator's Office and established within the Department of the Interior the Solid Fuels Administration for War with the Secretary of the Interior as Administrator. A Solid Fuels Advisory War Council, organized by the Secretary and composed of representatives of anthracite, bituminous coal, and coke producers, retail dealers, transporters, wholesalers, labor, and the public, met monthly in 1942 to assist and advise the Secretary on matters pertaining to coordination of the Nation's fuel supply to best meet wartime demands.

The needs of the Coordinator's Office for additional basic and current information, both economic and technical, regarding supplies and disposition of the solid fuels necessitated a substantial expansion in the work of the Bureau of Mines regarding these commodities. This applied particularly to coke, production of which could barely meet the needs arising from the great expansion in the metallurgical industries as a result of the war.

Federal Anthracite Coal Commission.—The Commission's report,[1] containing recommendations for both short-term and long-term measures of improvement, was prepared by the Commission after hearings in the Pennsylvania anthracite regions and study of special reports from Federal, State, and local governmental agencies, civic organizations, and private citizens. The investigation indicated that

[1] Economic Conditions in the Anthracite Coal Regions, House Document 709, 77th Congress, 2d Sess. April 21, 1942.

Digitized by Google

the anthracite area has substantial possibilities for industrial expansion. The measures recommended for immediate improvement called attention to the unused manpower with mechanical aptitude and industrious habits and to a reserve of housing facilities, and suggested that war plants, particularly those for the production of aluminum, zinc, castings, armor plate, machine parts, and ammunition, be established in the anthracite regions. The report urged that the industry continue the development of industrial and domestic stokers and automatic heating equipment and investigate ways to expand the industrial uses of anthracite. It was recommended also that current surveys on mine flooding be completed. The measure for long-term improvement included a recommendation that a research station under the direction of the Federal Bureau of Mines be located in the anthracite area to investigate new uses for anthracite, study mining methods, assist in the solution of acid and silt problems in the mine waters, and serve as headquarters for the engineering organization concerned with the industrial development of the area. It was suggested also that an agency be created to study the economic problems arising from the depletion of anthracite reserves and that a survey be made of the anthracite forest region with a view to reforestation.

Anthracite Committee.—Operators whose production represented more than 90 percent of the total output of the industry continued to function under the Voluntary Production-Control Plan for stabilizing the industry. The plan was inaugurated in January 1940 through the cooperation of the Commonwealth of Pennsylvania, the United Mine Workers of America, and the producers and was enacted into the laws of Pennsylvania in 1941. The committee kept in close contact with the illicit mining industry and made every effort to alleviate this highly unfavorable economic and social problem.

Anthracite Industries, Inc.—One of the immediate objectives of an expanded research program was the development of inexpensive auxiliary equipment to improve the efficiency and convenience of anthracite-burning equipment now in use. The plan also called for cooperation with equipment manufacturers to develop, design, and improve boilers, furnaces, tank heaters, stokers, and other types of equipment for burning anthracite. With new and improved heating equipment, the anthracite industry hopes to take a leading place in the postwar period and to compete successfully with other fuels. This research program is additional to current activities of the organization in assisting the plumbing trade, architects, real estate concerns, and Government agencies interested in the proper equipment for burning anthracite. The anthracite industry's laboratory at Primos, Pa., established standards to guide utilization engineers of the anthracite-producing companies in recommending grate equipment to convert oil-burning boilers and furnaces to anthracite.

Anthracite Institute.—The Anthracite Institute was particularly active in voicing its opposition to the proposed extension of natural-gas pipe lines into the vital eastern markets. In addition, its members represented the producers before various organizations and committees on other problems affecting the anthracite industry. Through its information services it kept the operators informed of pertinent State and Federal legislation, freight rates, Government regulations

Digitized by Google

and restrictions on the use of oil and gas for fuel, and many other matters important to the anthracite industry.

Labor.—In December 1942 about 19,000 men went on strike in the Wyoming region in protest against an increase of $6.00 a year in dues and assessments payable to their union, the United Mine Workers of America, and demanded a wage increase of $2.00 a day. A general suspension throughout the anthracite region was threatened. Representatives of the producers, the striking miners, and union officials were summoned before the War Labor Board, January 15, 1943, to state fully the reasons for the strike. After hearing the testimony of the interested parties, the Board ordered the miners back to work and suggested that grievances be adjusted through the machinery established in the contract between the producers and the union. Many of the miners refused to obey the order, and on January 19 the War Labor Board turned the case over to the President, who ordered the miners to resume work; within a few days all of them had returned to their jobs.

To meet increased demands for anthracite, the operators and miners agreed to extend the work week from 5 days to 6; the agreement stated that the mine workers were to be paid time and a half and rate and a half for the sixth consecutive day worked in any 1 week. The agreement was contingent on an increase of maximum prices of anthracite by the Office of Price Administration necessary to compensate for increased costs occasioned by payment of overtime for the sixth day. A price increase of approximately 50 cents a ton was authorized, effective January 9, 1943, and within a few weeks the industry commenced the 6-day week schedule.

Research.—In December 1942 the President approved S. 357, an act passed by the Senate and House of Representatives (56 Stat. 1056), providing for the establishment and operation of a research laboratory in the Pennsylvania anthracite region. Investigations and researches to be conducted through the laboratory facilities will relate to the mining, preparation, and utilization of anthracite; to the development of new uses and markets for anthracite and its products; to safety, health, and sanitation in mining operations; and to any other matters relating to problems of the anthracite industry. The laboratory is to be established, equipped, and maintained by the Secretary of the Interior, acting through the Bureau of Mines. The act authorized appropriation of $450,000 for the erection and equipment of the necessary buildings and $175,000 annually for the maintenance and operation of the experiment station.

The cooperative research program sponsored by the Commonwealth of Pennsylvania and the Anthracite Industry at Pennsylvania State College was continued, special attention being paid to the use of anthracite in water-gas generators and in the preparation of activated carbon.

Research undertaken by Anthracite Industries, Inc., is discussed elsewhere in this chapter under the subheading Anthracite Industries, Inc.

Competitive fuels in the United States and in principal markets.—More than 95 percent of the anthracite shipped from the mines to points in the United States is destined to the New England States, New York, New Jersey, Pennsylvania, Maryland, Delaware, and the District of Columbia. Data on the consumption of all fuels in these

Digitized by Google

markets are not available; however, the apparent consumption of anthracite, coke, briquets, and heating and range oils, in terms of anthracite, amounted to 84,831,000 net tons in 1941. The sales of heating and range oils in this area in 1941 were the equivalent of 33,284,000 tons of anthracite, and the mine shipments of anthracite to these States totaled 47,466,000 tons. According to the Pennsylvania State Department of Mines, anthracite rail and truck shipments in 1942 to this area totaled 51,546,000 tons. In addition, considerable quantities of "bootleg" or illicit coal were shipped to these markets. The demand for coke for metallurgical use was chiefly responsible for the decline in its consumption for domestic heating from 4,052,000 tons in 1940 to 3,169,000 tons in 1942. Details are shown in table 3.

TABLE 3.—*Apparent consumption of anthracite and selected competitive fuels in the principal anthracite markets, 1939–42*

In general, the supplies of fuel commonly used for space heating in the United States increased in 1942 over 1941. The increase in anthracite was quite pronounced; coke sales declined, and although data for 1942 on sales of heating and range oils are not available, it is not believed that the use of oil increased appreciably. Details on supplies of various fuels are given in table 4.

TABLE 4.—*Total supplies of fuels commonly used for space heating purposes in the United States, 1924 and 1939–42*

[Wherever available, figures represent quantity actually consumed for domestic heating or for space heating offices, apartments, hotels, schools, hospitals, etc. Where such figures are not available but where the fuel is known to be used chiefly for domestic or space heating purposes, total production (or imports) is shown to indicate trend of growth]

[1] A considerable part of the smaller steam sizes is used by industries, railroads, and public utilities.
[2] Production plus imports less exports.
[3] Partly estimated.
[4] Data not available.
[5] An estimated one-half is used for domestic purposes.
[6] Exact data not available; estimated between 55 and 77 million tons a year, including lignite. Anthracite and semianthracite outside Pennsylvania shown separately.
[7] Includes all grades of fuel oil used for heating buildings.
[8] Includes gas used for heating offices, hotels, apartments, schools, hospitals, and stores and other large buildings, as well as houses.
[9] American Gas Association.

Transportation and distribution of anthracite to principal markets.—According to data compiled from records of the Pennsylvania State Department of Mines, the shipping of anthracite from mines to mar-

Digitized by Google

kets by trucks has been increasing continuously since 1936, when truck coal totaled 3,177,656 net tons. In 1941 and 1942 the trucked coal amounted to 7,529,479 and 7,955,738 tons, respectively, and in each year comprised 15 percent of the total shipments of anthracite to destinations in the United States. These tonnage figures represent legitimate coal only and do not include the production from illicit or "bootleg" mines, nearly all of which is trucked to market. Legitimate coal is trucked not only to the ultimate consumer but to many retail dealers within a radius of 150 miles of the anthracite-producing regions.

In 1942 Pennsylvania received 71 percent of the total trucked shipments; New Jersey and New York followed, with 15 and 11 percent, respectively. Before 1941 most of the anthracite moved by truck was shipped during December, January, February, and March;

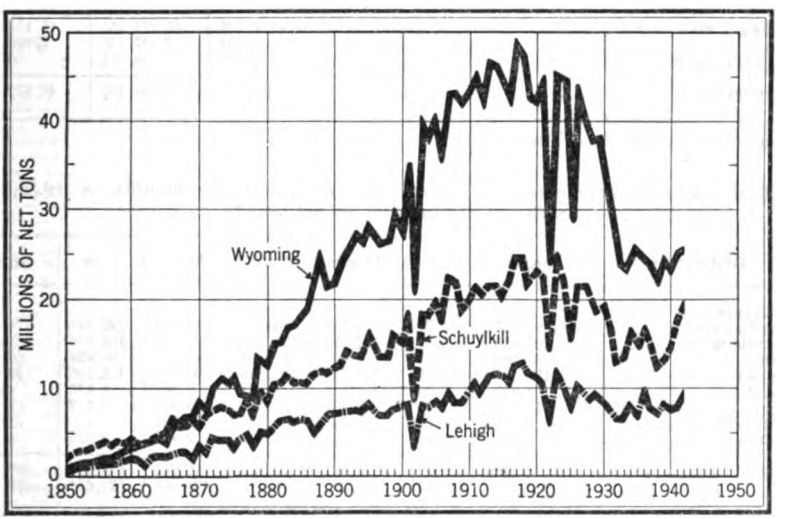

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1850–1942.

however, in 1941 and 1942, because of increased demand for coal, monthly shipments were fairly uniform throughout the year.

Anthracite shipments, by States of destination, for 1940–42 are shown in table 5, and truck movement of anthracite, by months, for 1941 and 1942 is given in table 6.

According to the Commonwealth of Massachusetts, Division on the Necessaries of Life, rail receipts of Pennsylvania anthracite in New England in 1942 totaled 5,393,475 net tons, a gain of 10.8 percent over 1941: Tidewater receipts, including a small amount of imports, were 580,625 net tons in 1942, a decrease of 14.8 percent from 1941. Table 7 gives details of anthracite moved to New England.

Loadings at Lake Erie ports increased from 536,490 tons in 1941 to 575,176 tons in 1942. Receipts on the upper Lake docks declined from 534,357 tons in 1941 to 443,233 tons in 1942.

Figure 1 illustrates graphically shipments of anthracite from the Lehigh, Schuylkill, and Wyoming regions, 1850–1942.

[1] Compiled from reports of Pennsylvania Department of Mines.

Consumption.—Consumption of anthracite in the United States in 1942, including colliery fuel, amounted to 56,500,000 net tons, an increase of 3,800,000 tons over the calculated consumption in 1941. These figures consider imports and exports of anthracite and changes in producers' stocks but do not allow for changes in stocks held by retail dealers and small consumers, as data on variations of stocks of

Digitized by Google

these groups were insufficient. The over-all increase in consumption can be attributed largely to increased industrial use and the substitution of anthracite for fuel oil and coke where shortages of these fuels developed in the principal anthracite markets. Electric power utilities and class I railroads consumed 4,009,095 tons of anthracite in 1942 compared with 4,289,936 tons in 1941.

Changes in stocks.—Anthracite producers found it necessary to draw on stocks to meet the 1942 demands. Stocks of 1,273,788 net tons on December 27, 1941, fell to 797,815 tons by January 2, 1943. As the greatest demand was for Egg, Stove, and Nut sizes, the coal in storage on the latter date was largely Pea and smaller, and very little of the domestic sizes was available.

TABLE 7.—*Receipts of anthracite in New England, 1917, 1920, 1923, and 1927–42, in thousands of net tons*

[1] Commonwealth of Massachusetts, Division on the Necessaries of Life.
[2] Department of Commerce.
[3] Total receipts by rail and by tide less imports.
[4] Preliminary figures.

Stocks held by 159 selected dealers declined from 417,988 net tons in January 1942 to 282,965 tons in September and at the close of the year amounted to 348,057 net tons.

Stocks held by electric power utilities and railroads (class I) amounted to 1,774,483 tons on December 31, 1942, compared with 1,496,349 tons on the same date in 1941; stocks held by public utilities increased 26 percent, whereas those of railroads declined 18 percent. Stocks on the upper Lake docks declined from 273,727 tons on December 31, 1941, to 160,998 tons on December 31, 1942.

Illicit coal.—According to the Anthracite Committee, the output of anthracite by the illicit or "bootleg" mining industry amounted to 3,931,000 net tons in 1942, a substantial decrease from the estimated production of 5,000,000 tons in 1941. The decline in output can be attributed largely to the efforts of the committee in arranging for the employment of former "bootleggers" by legitimate companies, as well as to the loss of manpower in the illicit industry because many had taken jobs in near-by war industries. A survey by the committee

Digitized by Google

in March 1941 indicated that 10,762 men were working 3,006 "bootleg" holes, whereas in May 1942 a comparable survey revealed 7,554 men employed in 2,029 holes. In April 1943 the number of holes had decreased to 1,151 and the men employed totaled 3,100. Sixty-five men were killed in "bootleg" mining in 1940, 54 in 1941, and 49 in 1942.

Trend of employment.—The employment and production trends of the anthracite industry have been consistently downward from 1926 (when the number of employees totaled 165,386 and the output was 84,437,000 net tons) to 1941. The production curve reversed itself in 1941 and 1942, when the demand for anthracite increased sharply under the stimulus of war; but the number of employees continued to decline until, at the close of 1942, a shortage of several thousand men below the number necessary to meet production requirements existed within the industry. Employment declined from an average of 88,054 men in 1941 to 82,121 in 1942. The induction of men into the armed forces and the loss of others to near-by war industries were largely responsible for the decrease. These figures do not include men working in "bootleg" holes. Data on employment are given in table 21.

Trend in prices.—In January 1942 circular f. o. b. mine prices for anthracite were quoted as follows: Broken, Egg, Stove, and Chestnut, $6.75 a net ton; Pea $5.25 a ton; Buckwheat, Rice, and Barley, $3.75, $2.90, and $2.15 a ton, respectively. On March 30, 1942 the Office of Price Administration issued Maximum Price Regulation 112, establishing, as maximum prices, those then in effect, which were the same as the January quotations. The regulation also required the granting of seasonal discounts on domestic sizes as follows: April, 50 cents a net ton; May, 40 cents; June, 25 cents; and July, 10 cents. Immediately following issuance of the March 30 price regulation, representatives of the anthracite industry met with price-administration officials on several occasions and urged not only elimination of the discount requirements but also an increase in coal prices. On April 16, 1942, the Price Administrator issued an amendment to Price Regulation 112 which eliminated the seasonal discount and at the same time refused the industry's requests for a 25-cent-per-net-ton price increase for domestic and Pea sizes over the maximum prices established in Price Regulation 112.

Effective January 9, 1943, the Office of Price Administration authorized an increase in maximum prices of anthracite of approximately 50 cents a net ton. The price increase reflected higher production costs incident to extension of the work week from 5 to 6 days, and the payment of time and a half and rate and a half for the sixth consecutive day worked in any 1 week. The new prices, as of January 9, 1943, were $7.30 per net ton f. o. b. mine for Broken, Egg, Stove, and Chestnut sizes; $5.75 for Pea; and $4.20, $3.35, and $2.50 for Buckwheat No. 1, Rice, and Barley sizes, respectively.

Retail prices of anthracite, bituminous coal, coke, and heating oil in selected cities, by months, in 1941 and 1942, are shown in table 8. These prices were compiled from reports of the Bureau of Labor Statistics, United States Department of Labor.

Sales realization.—The average realization on breaker shipments increased from $4.59 a net ton in 1941 to $4.79 in 1942—an increase of 4.4 percent. The average value per net ton of the total anthracite production in 1942 was $4.50 compared with $4.26 in 1941.

Freight rates.—A number of changes affecting the freight-rate structure for anthracite were authorized by the Interstate Commerce Commission in 1942. The so-called motor-compelled rates, which were originally established to compete with the trucking of anthracite, were to expire on December 20, 1942, but were extended to June 20, 1943. Early in 1942 the railroads were authorized to increase freight rates on all commodities, the specific increases on coal being 3 cents per net ton for rates of $1.00 or less and 5 cents per net ton for those over $1.00 a ton. The authorization was issued by the Interstate Commerce Commission on March 2, 1942, and the charges were made effective not later than May 15, 1942. The increases as approved were for the war period and 6 months thereafter. Late in 1942 the Office of Price Administration filed a petition with the Commission asking for reopening of the case and reconsideration with a view to discontinuation of the increases allowed, pointing out that the increases were granted primarily to produce additional revenue for the railroads but that earnings would now be exceedingly favorable if the adjustments granted had not been in effect. In April 1943 the Commission ordered cancellation of the increases, effective May 15, 1943, for a temporary period ending December 31, 1943, during which time further consideration will be given to the comprehensive record along with the developments during the interim. Late in 1942 an examiner of the Interstate Commerce Commission recommended a reduction of 46 cents a gross ton in anthracite freight rates from the mines to New York tidewater piers. The recommendation was argued by interested parties before the Commission in April 1943, and the final decision of that body is pending. The revenue act of 1942 imposed a tax on the transportation of anthracite amounting to 4 cents a net ton, effective December 1, 1942.

Imports and exports.—Exports of anthracite increased from 2,667,632 net tons in 1940 to 3,380,189 tons in 1941 and reached a total of 4,438,589 tons in 1942—the greatest tonnage exported since 1923, when shipments were 5,090,138 tons. Almost all exports were destined to Canada, where a shortage of coke and restrictions on the use of heating oils and gas created a heavy demand for Pennsylvania anthracite. The shipments to Canada were largely domestic sizes, and the industry hopes that gains in this market will be retained after the war. Exports were valued at $21,210,499 in 1940, $27,691,017 in 1941, and $38,286,755 in 1942. Anthracite imports declined from 135,436 tons in 1940 to 74,669 in 1941 and then increased to 140,774 tons in 1942. (See tables 30 to 32.)

Mechanical stokers and oil burners.—Government restrictions on the manufacture and installation of stokers and oil burners were largely responsible for the sharply reduced sales of this equipment in 1942. According to the Bureau of the Census, United States Department of Commerce, factory sales of mechanical stokers (class 1) for burning anthracite decreased from 17,110 units in 1941 to 11,562 in 1942. Sales of class 2 stokers (capacity 61 to 100 pounds of coal per hour) declined from 599 in 1941 to 356 in 1942.

Shipments of oil burners fell from 303,869 units in 1941 to 131,031 in 1942. These figures do not include burners used in water heaters, stoves, ranges, and space heaters, but do include both domestic and foreign shipments.

SOURCES AND ACKNOWLEDGMENTS

Annual statistics of the Pennsylvania anthracite industry are prepared, for the most part, from reports received direct from the producers and shippers of anthracite, as a result of a canvass conducted by mail. More than 95 percent of the tonnage is reported in this manner, and the remainder is obtained personally by a representative of the Bureau of Mines or from reliable collateral evidence. The information as furnished by the producers is voluntary and is held confidential, as is customary with the statistical services of the Bureau of Mines.

In compiling available information, pertinent statistics prepared by the Anthracite Committee, the Anthracite Institute, the American Association of Railroads, and the Pennsylvania Department of Mines have been used to advantage. The Bureau of Mines gratefully acknowledges the cooperation of these and others from whom information has been received.

PRODUCTION

Production of Pennsylvania anthracite in 1942 totaled 60,328,000 net tons—an increase of 7 percent over the output of 56,368,000 tons in 1941. These statistics include deep-mined and strip-pit production, culm-bank coal, anthracite purchased by the legitimate industry from "bootleggers," and river or dredge coal, which is recovered from the rivers and creeks draining the anthracite fields. Also included is a small amount of semianthracite produced in Sullivan County (48,213 net tons in 1942).

See tables 9 to 18 for production and shipments by regions, fields, and counties.

Before 1930 anthracite was mined only by companies who owned or leased the coal lands. During the depression years of the early 1930's unemployed miners dug anthracite from lands of the operating companies without the permission of the owners or lessees, and trucks transported the coal to distant cities where it was sold in competition with the legitimate product. In 1941 the illicit coal tonnage was estimated at about 5,000,000 net tons, and in 1942 the Anthracite Committee estimated "bootleg" production at 3,931,000 tons. Before 1941 "bootleg" coal was not included in the production statistics of the Pennsylvania anthracite industry by the Bureau of Mines. In 1941, however, legitimate operators lawfully purchased run-of-mine coal from "bootleggers" and shipped 1,902,481 tons of the prepared product to market, and in 1942 the purchases totaled 2,616,839 tons. It would be impractical to segregate this purchased "bootleg" coal from the output of the legitimate industry, and it is therefore included in the various production tables in the Minerals Yearbook chapters on Pennsylvania anthracite for 1941 and 1942. For this reason, the production statistics for those years are not exactly comparable with previous years. No attempt has been made to include in the statistics "bootleg" coal other than that purchased by legitimate operators. To compute the output per man per day for the anthracite industry in 1941 and 1942, it was necessary to deduct the "bootleg" purchases from the total tonnage shipped by the legitimate industry since adequate data on man-hours required to produce the bootleg tonnage

Digitized by Google

are not available. Details of this procedure are discussed in this chapter under Labor Statistics.

Weeks and months.—Tables 9 and 10 summarize the statistics of weekly and monthly production of anthracite. Statistics of current output are estimated from records of car loadings and other pertinent data. The weekly and monthly figures in tables 9 and 10 have been adjusted to the annual total ascertained by direct canvass of the operators.

[1] Production is estimated from weekly carloadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal. Monthly statistics from 1905 to 1925 will be found in Mineral Resources, 1925, pt. II, pp. 427–428, and from 1925 to 1930 in Mineral Resources, 1930, pt. II, p. 741.

[2] Includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.

[1] Value given is value at which coal left possession of producing company; does not include margins of separately incorporated sales companies.
[2] For purposes of historical comparison and statistical convenience, the mines of Sullivan County are grouped with the Pennsylvania anthracite region, although the product is classified as semianthracite according to the American Society for Testing Materials Tentative Standard.

Digitized by Google

Small mines and intercompany sales.—Many small, independently owned mines produce run-of-mine anthracite, which is shipped by rail or truck to breaker companies for preparation and transportation to market. Also, a number of the larger companies have built central cleaning plants for preparing run-of-mine coal from their own mines. This tendency within the industry of transferring run-of-mine coal from one company to another and the trend toward central preparation plants have increased the complexity of compiling the statistics; however, every effort has been made to avoid any duplication of tonnage. The men employed in producing run-of-mine coal have been included in the labor statistics and are an appreciable part of the total number of employees engaged in production work. This reference to independently owned mines concerns legitimate operations only and should not be confused with illicit or "bootleg" mines, for which complete employment data are not available.

Regions, fields, and counties.—The main anthracite region covers an elongated area of about 480 square miles in eastern Pennsylvania, with its longer axis running northeast and southwest. The area is divided into three regions—Lehigh, Schuylkill, and Wyoming. This classification is generally used by the trade, and it is also followed in the district organization of the United Mine Workers of America, in which district 1 corresponds to the Wyoming region, district 7 to the Lehigh region, and district 9 to the Schuylkill region. The Wyoming region covers a single geologic anthracite basin and is about 54 miles long by 6 miles wide at its widest point; the Lehigh region comprises the anthracite lands tributary to the Lehigh River that forms its eastern boundary and contains the Eastern Middle field and the section of the Southern field lying east of Tamaqua; and the Schuylkill region consists of the Western Middle field and the section of the Southern field lying west of Tamaqua.

The area is divided also into four fields, using the grouping of the anthracite geologic basins as a framework, as follows: The Northern field, which is the same as the Wyoming region; the Eastern Middle or Lehigh field, which consists of a group of at least 10 small basins; the Western Middle field, a single basin about 36 miles long by 4½ miles at its widest point; and the Southern field, also a single basin, about 54 miles long by 6 miles at its widest point, which breaks into a long "fishtail" toward its western ends.

TABLE 12.—*Pennsylvania anthracite produced, 1938–42, by fields, in net tons*

[The figures of breaker product include a certain quantity of culm-bank coal, which amounted to 2,648,273 tons in 1942. Data for 1913–25 will be found in Mineral Resources, 1925, pt. II, p. 517, and for 1919–30 in Mineral Resources, 1930, pt. II, p. 747]

AVERAGE SALES REALIZATION

The valuation figures in this study represent values at the breaker or washery as reported by the operating companies. The reporting companies are requested to "estimate value of the product not sold" and to "exclude selling expenses" in making their reports.

From this it will be seen that when a producing concern sells its output to a separately organized sales company, the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal is placed on the general market. This fact should be borne in mind in considering the variations in value among different regions, shown in tables for the same sizes of coal.

The average sales realization per net ton on breaker shipments was $4.79 in 1942 compared with $4.59 in 1941 (see table 19). If local sales, colliery fuel, and washery and dredge coal are included, the average value per net ton of the total 1942 production was $4.50 compared with $4.26 in 1941 (see table 20).

LABOR STATISTICS

A labor shortage of several thousand men developed in the Pennsylvania anthracite industry in 1942, when the average number of men employed was 82,121—a decrease of 5,933 from the total of 88,054 men employed in 1941. Many men formerly employed in the anthracite mines entered the armed forces, and others obtained employment in near-by war industries.

The employment statistics in this chapter do not include workers in "bootleg" or illicit coal mining, which is conducted in the Southern and Western Middle fields of the Pennsylvania anthracite regions. According to the Anthracite Committee, 10,762 men were working 3,006 "bootleg" holes in March 1941, and in May 1942 a comparable survey revealed 7,554 men employed in 2,029 holes. Although these workers are not included in the employment data, the coal produced by some of them was purchased by the legitimate industry for preparation and shipment to market, and coal so purchased is included in the production tables of this chapter. Complete employment data for the "bootleg" holes from which this coal was produced are not available. In calculating the output per man per day, therefore, the tons of "bootleg" coal purchased by the legitimate industry were deducted from the total tonnage reported by the operators, and the resulting legitimate production was then used to calculate the output per man per day. It is true that part of the time of the men employed at the preparation plants of the legitimate companies was used to prepare this purchased coal for market; however, on a per-ton basis this time is very small, and its omission will not detract materially from the validity of the result obtained.

See tables 21 to 23 for details on labor statistics.

EQUIPMENT AND METHODS OF MINING

Mechanical loading.—The quantity of coal loaded mechanically underground increased from 13,442,000 net tons in 1941 to 14,741,000 tons in 1942. Hand-loaded tonnage amounted to 30,435,000 tons in

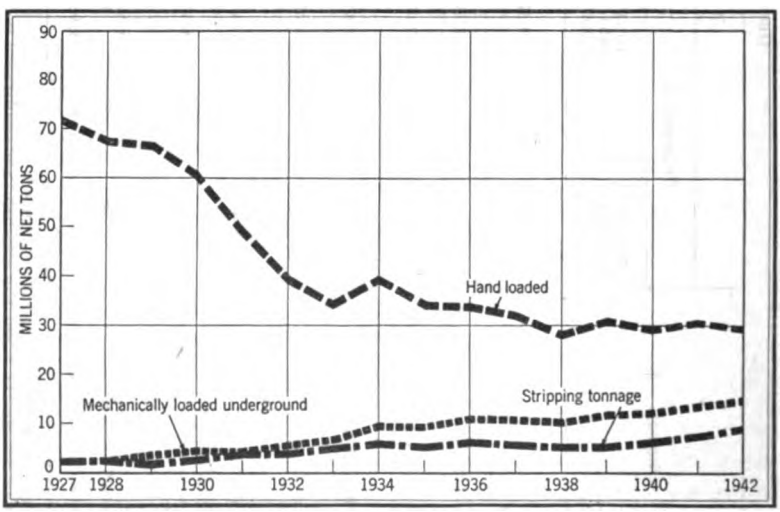

FIGURE 2.—Relative growth of mechanical loading, hand loading, and stripping of Pennsylvania anthracite, 1927–42.

Digitized by Google

1941 and increased to 30,495,000 in 1942. Details are shown in tables 24 to 26. Figure 2 illustrates graphically the relative growth of underground mechanical and hand loading and of stripping in the Pennsylvania anthracite region, 1927–42.

Cutting machines.—The quantity of anthracite cut by machines increased from 1,855,000 net tons in 1941 to 2,286,000 tons in 1942. Details are shown in table 27.

Strip-pit operations.—The demand for anthracite caused a rapid expansion of strip-pit activities, and the tonnage recovered by this method of mining increased from 7,317,000 net tons in 1941 to 9,071,000 tons in 1942. In 1942, 16.7 percent of the fresh-mined coal was recovered from strip pits compared with 14.3 percent in 1941. For details of strip pit mining see table 28. Figure 3 illustrates graphically the production of anthracite from strip pits, by regions, 1927–42.

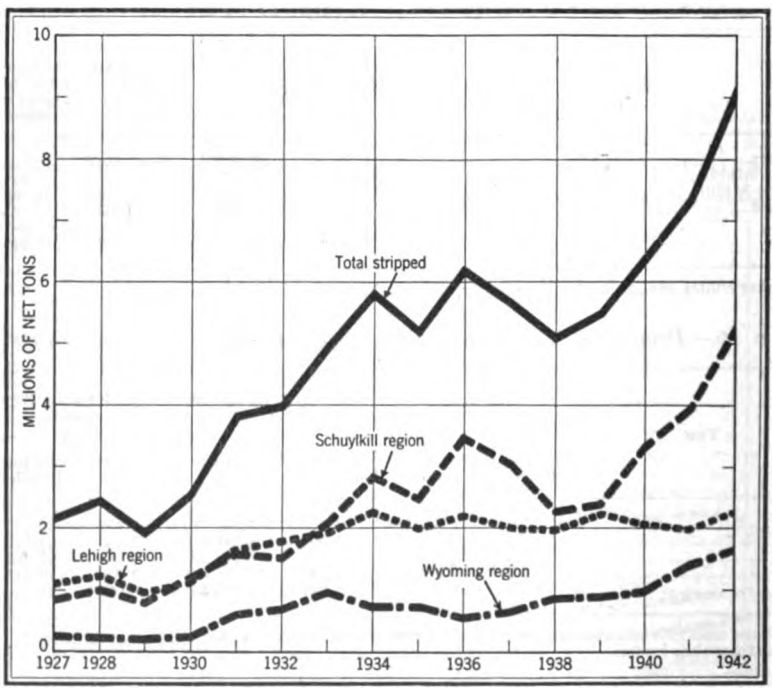

FIGURE 3.—Pennsylvania anthracite mined from strip pits, by regions, 1927–42.

Dredge operations.—Anthracite recovered from the rivers and creeks draining the anthracite fields totaled 1,285,000 net tons in 1942, a decrease from 1,518,000 tons in 1941. For detailed statistics by rivers see table 29.

	1,285,033	1,478,719	1.15

FOREIGN TRADE [2]

Anthracite exported from the United States in 1942 totaled 4,438,589 net tons compared with 3,380,189 tons in 1941. Virtually all of the exported coal was shipped to Canada where shortages of heating gas and coke created a strong demand for anthracite. The tonnage exported in 1942 was the largest since 1923 when the total exports were 5,090,000 net tons. Details of imports and exports are shown in tables 30 to 32.

Canadian market.—Coal available for consumption in Canada in 1942 (changes in stocks not considered) increased about 10.5 percent over 1941 and set an all-time high record. Increases were shown in each category—production, imports, and exports. Production of bituminous coal, subbituminous coal, and lignite increased nearly 3.4 percent; imports of anthracite 22 percent and of bituminous coal 16.5 percent. Although country of origin is not disclosed, virtually all of the anthracite and bituminous coal originated in the United States. Exports of bituminous coal increased more than 53 percent.

Although not disclosed by the Canadian records, United States Custom House statistics show that imports of coal from Canada are mainly into the Maine and New Hampshire and the Montana and

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

Idaho custom districts and that in 1942 imports into Montana and Idaho were more than 220,000 tons—an increase of 77 percent over 1941. A large part of this tonnage probably was for consumption in the State of Washington. American consuls report a marked decline in coal production in British Columbia in the first part of 1943 as compared with 1942.

See table 33 for statistics on coal and coke in Canada.

SUMMARY

The year 1942 witnessed a new high coke-production record for the United States in response to the heavy demand of the expanded iron and steel industry for metallurgical fuel. The total output of byproduct and beehive coke was 70,568,944 net tons—an increase of 5,382,366 tons (8 percent) over the last previous high record in 1941. Of the amount of coke produced in 1942, byproduct ovens supplied 62,294,909 tons (88 percent) and beehive ovens 8,274,035 tons (12 percent). Byproduct-coke production increased 3,812,487 tons (7 percent) in 1942 compared with 1941, and the production of beehive coke increased 1,569,879 tons (23 percent). The average daily rate of byproduct output increased steadily throughout the year; the average daily rate of beehive remained fairly constant.

Although the 1942 output from beehive ovens represented only 12 percent of the Nation's total coke production, its contribution to the 1942 war program was noteworthy. Of the 7,309,337 tons of beehive coke produced in Pennsylvania, 6,561,085 tons (90 percent) were used in blast furnaces (table 28), mostly in the Pittsburgh district, where pig iron production would have been seriously hampered without the supply from nearby beehive-coke plants.

The total value of coke, breeze, and tar produced and of other byproducts sold in 1942 was $629,408,422 (an increase of 17 percent over 1941) and exceeded that of any previous year. The greatest increase was in the value of byproduct coke produced, which rose from $316,477,231 in 1941 to $378,011,967 in 1942—an increase of

Digitized by Google

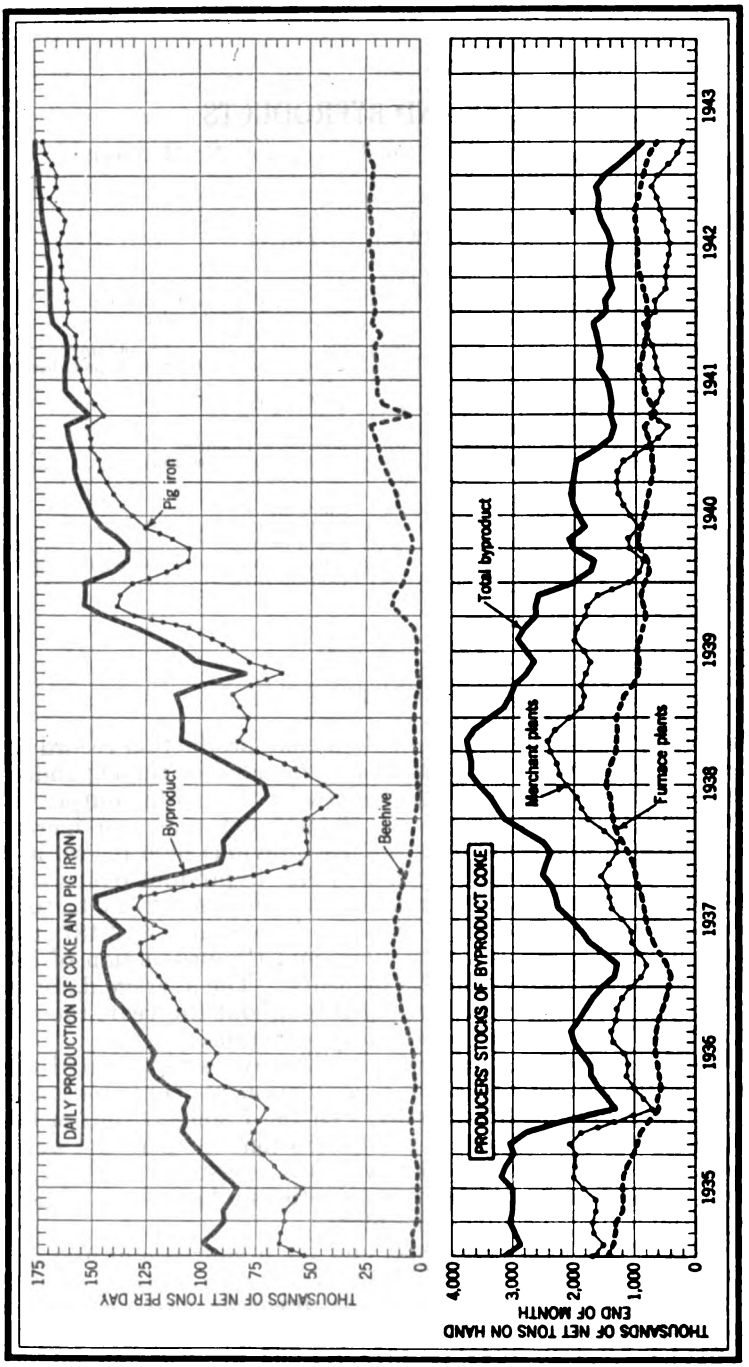

FIGURE 1.—Average daily production of beehive and byproduct coke and pig iron and producers' stocks of byproduct coke, 1935–43, by months.

Digitized by Google

19 percent; the value of byproducts sold rose from $158,809,184 to $176,932,465—an increase of 11 percent for the same period.

The production of screenings or breeze in 1942 was 4,751,683 tons and exceeded the 1941 output by 197,170 tons; the average receipts from sales of breeze increased from $2.35 a ton in 1941 to $2.63 in 1942.

The total calculated consumption of coke for all uses in the United States in 1942 was 70,107,181 tons. The principal use was in blast furnaces, and the quantity used by the producers, sold to financially affiliated corporations, or sold to other companies for blast-furnace use was 55,491,570 tons—an increase of 5,037,245 tons (10 percent) over the 1941 figure. Coke used for other purposes (in foundries, for the manufacture of producer gas and water gas, and for other industrial purposes) totaled 9,190,418 tons. Coke sold for domestic use was reported as 6,061,694 tons compared with 6,682,959 tons in 1941. The continued decrease in the quantity of coke used for domestic heating in 1942 emphasized the demand of the iron and steel industry.

Ceiling prices for coke were established by the Office of Price Administration on issuance of Maximum Price Schedules 29, 77, and 121, with subsequent amendments. The average receipts per ton of coke sold by producers in 1942 were as follows: Furnace, $6.16 per ton—an increase of $0.53 over 1941; foundry coke, $9.75—$0.40 higher than the 1941 price; coke used in the manufacture of water gas, $7.53—$0.79 higher than the price in 1941; other industrial, $6.88—an advance of $0.50 above the 1941 price; and domestic coke, $7.84—an increase of $0.91.

Total requirements in 1942 exceeded the output, and producers' stocks of coke totaled 1,489,049 tons at the end of the year—a reduction of 269,037 tons in stocks. Stocks of domestic coke decreased 344,285 tons; stocks of furnace coke increased 76,543 tons.

The accelerated rate of byproduct-coke-oven operations resulted in substantial increases in the output of gas, tar, crude light oil, and ammonia. The quantity of gas produced totaled 944,879,637 M cubic feet in 1942—a gain of 52,059,826 M cubic feet (6 percent) over the 1941 figure. Crude coal-tar output showed an increase of 36,026,151 gallons (5 percent) and reached an all-time record of 740,175,619 gallons.

Production of ammonium sulfate or equivalent increased from 1,741,503,884 pounds to 1,805,025,721 pounds (4 percent); the production of crude light oil increased from 231,358,897 gallons to 246,024,882 gallons (6 percent).

GOVERNMENT CONTROL MEASURES

The importance of coke and coke byproducts in time of war was recognized by the various war agencies, and a number of regulatory measures were established for the conservation, efficient utilization, and price control of the products derived from the carbonization of coal. A brief summary of the more important regulations follows:

Byproduct coke.—Office of Price Administration Maximum Price Schedule 29, issued August 30, 1941, effective October 1, 1941, froze prices of byproduct-foundry and byproduct-furnace coke at the levels prevailing October 1, 1941. Amendment 1, issued February 4, 1942, and effective February 7, equalized regional prices not covered in the original order; Amendment 2, issued January 28, 1943, retroactive to December 1, 1942, allowed the transportation-tax charge

Digitized by Google

of not more than 4 cents per ton of coke to be passed on to consumers, provided that the producers had paid a similar tax on the coal used to produce the coke.

Beehive coke.—Maximum Price Schedule 77, effective January 26, 1942, established a $6.00 per ton price on all beehive-furnace coke produced in Pennsylvania. Amendment 1 to revised Price Schedule 77, effective April 11, 1942, established a provision in which adjustments and exceptions could be presented; Amendment 2, effective August 12, raised the price to $6.50 for hand-drawn coke, where coal was trucked; Amendment 3 allowed the transportation-tax charge of not more than 4 cents per ton of coke to be passed on to consumers, provided that the coke-plant operator had paid a similar tax on coal charged into ovens.

In order that ceiling prices on all other coke produced not covered by Schedules 29 and 77 could be established, Maximum Price Schedule 121 was issued, effective May 18, 1942, which established maximum prices upon the basis of average prices over the period from December 15 to 31, 1941.

Benzol.—War Production Board General Preference Order M–137, issued April 20, 1942, effective June 1, placed benzol under complete allocation. This order was amended July 1, and deliveries and acceptances were placed under the supervision of the Director General for Operations. In December 1941 quotations on benzol, toluol, and xylol were stablized at not more than 1 cent a gallon above the average for the last quarter of 1941 at the request of the Office of Price Administration, and on March 11 this request was extended to keep current quotations in effect at least until July 1, 1942. In June 1942 the Office of Price Administration announced that quotations on light-oil derivatives would remain unchanged to December 31, 1942.

Toluol.—General Preference Order M–34, issued August 8, 1941, effective August 28, 1941, placed toluol under allocation. Amendments effective December 30, 1941, and May 22, 1942, further restricted uses and increased regulations, and beginning early in January 1942 no toluol could be exported without authorization from the Director of Priorities.

Xylol.—Xylol and xylol-range aromatic materials derived from coal tar were brought under General Preference Order M–150 by the issuance, in July 1942, of Amendment 1. This amendment restricted sales and deliveries of xylol and xylol-range aromatic materials to orders with a preference rating of A–2 or higher.

Ammonium sulfate.—This byproduct was placed under allocation by the War Production Board on June 1, 1942, through the issuance of General Preference Order M–163. Maximum prices for ammonium sulfate were governed by Maximum Price Schedule 205, issued by the Office of Price Administration, effective August 22.

Pyridine.—Production and distribution of pyridine were placed under complete allocation by the War Production Board through Conservation Order M–185, effective September 1. In addition to its use in the manufacture of sulfa drugs, pyridine is employed in manufacturing a water repellant.

TECHNOLOGIC DEVELOPMENTS

War activities in 1942 augmented the demand for metallurgical coke. Iron-production requirements emphasized the need for the

Digitized by Google

best possible grade of coke for blast-furnace use. The Bureau of Mines undertook investigations to assist the coke producers to meet the needs of blast furnaces as to available supply and quality. An industry committee, working in cooperation with the Office of Solid Fuels Coordinator for War, the War Production Board, and the Bureau of Mines, advises the investigators of the most pressing needs and through cooperation and advice facilitates the research work to be done.[1]

The addition of 4 percent of anthracite fines (No. 5 Buckwheat) to the coking-coal mix was practiced at the Laclede Gas Light Co., St. Louis, Mo., in 1942. It was reported that the quantity of large-size foundry coke produced doubled and that it was possible to carbonize 13 percent more coal per day because the coking time normally required for foundry coke was reduced from 26 hours to 18¾.[2]

Extensive research work was done in 1942 by the Koppers Co. concerning new methods of heating Koppers-Becker coke ovens The new heating methods were radical in departure from methods used in former years by this company, and it is reported that the research resulted in a coke-oven design that not only improved coke quality but also permitted more efficient economics of oven operation by simplifying operating technique.[3]

TABLE 1.—*Salient statistics of the coke industry in 1942*

	Byproduct	Beehive	Total
Coke produced—			
At merchant plants:			
Quantity.....net tons	15,134,866		15,134,866
Value	$114,723,148		$114,723,148
At furnace plants:			
Quantity.....net tons	47,160,043		47,160,043
Value	$263,288,819		$263,288,819
Total:			
Quantity.....net tons	62,294,909	8,274,035	70,568,944
Value	$378,011,967	$47,601,777	$425,613,744
Screenings or breeze produced:			
Quantity.....net tons	4,600,030	151,653	4,751,683
Value	$10,897,121	$151,210	$11,048,331
Coal charged into ovens:			
Quantity.....net tons	87,973,821	12,875,812	100,849,633
Value	$385,007,197	$32,458,011	$417,465,208
Average value per ton	$4.38	$2.52	$4.14
Average yield in percent of coal charged:			
Coke	70.81	64.26	69.97
Breeze (at plants actually recovering)	5.30	2.46	5.11
Ovens:			
In existence January 1	13,016	18,669	31,685
In existence December 31	13,303	[1] 16,295	29,598
Dismantled during year	136	1,486	1,622
In course of construction December 31	1,327		1,327
Annual capacity of ovens December 31.....net tons	64,554,972	10,408,595	74,963,567
Coke used by producer—			
In blast furnaces:			
Quantity.....net tons	41,602,950	701,830	42,304,780
Value	$230,691,580	$4,028,121	$234,719,701
To make producer gas:			
Quantity.....net tons	810,492		810,492

[1] Furnace and foundry coke only.
[2] Before 1934, figures represent general imports; beginning with 1934, they represent imports for consumption only.
[3] "For all other purposes" included under "Other industrial (including producer and water gas)."
[4] Number of ovens in existence at plants that operated in 1942 as reported by operators.

SCOPE OF REPORT

This report presents final statistics of the byproduct- and beehive-coke industry in 1942. In addition to the customary annual data, the results of a survey covering operations of coal-gas plants in 1942, made by the Bureau of Mines for the first time, are presented in this chapter.

In the United States coke is produced by a group of four different industries. In addition to that manufactured in the familiar byproduct and beehive ovens, coke is obtained in the refining of petroleum and of tar and in the manufacture of coal gas. The coke produced by each of these processes, however, differs greatly in character, and the problems affecting each are separate and distinct.

Digitized by Google

In 1942, 1,338,000 tons of petroleum coke and 117,714 tons of coal-tar-pitch coke were produced, compared with 1,648,000 and 91,800 tons, respectively, in 1941. The decrease in output of petroleum coke in 1942, in spite of increased requirements, was due to fuel-oil shortages, which forced several large refineries to eliminate coke production.

Since, in general, only coke from byproduct and beehive ovens is adapted to blast-furnace and foundry use and since most of all coke produced is directed to these uses, the coke trade is concerned more especially with byproduct and beehive coke; hence the statistics of this report relate especially to these two coke-manufacturing processes.

The standard unit of measurement in the coke industry is the short or net ton of 2,000 pounds, and unless otherwise specified that unit is employed throughout this report.

COKE AND COKE BREEZE

MONTHLY AND WEEKLY PRODUCTION

Figures for monthly and weekly production of coke are given in tables 3 to 7. The monthly and weekly production of byproduct coke is based upon reports from operators. In February 1942 the Bureau of Mines renewed the collection of weekly production data from the byproduct-coke industry—the first time since 1918. This canvass was undertaken at the request of the Office of Solid Fuels Coordinator [4] for War in order that weekly production trends in the byproduct-coke industry could be ascertained. The demand for coke was so great in 1942 that maximum output was necessary to meet the increased requirements of the war industries, and the daily rate of production rose steadily throughout the year.

The current weekly statistics of beehive coke, shown in table 6, are estimates based upon weekly carloadings on the principal coke-carrying railroads, on shipments over private railroads, and on amounts known to have been consumed by associated steel works close to the producing ovens. As beehive coke seldom is stored at the ovens in any great quantity, shipments are a good barometer of weekly production. The collection of monthly data from beehive-coke-plant operators was begun by the Bureau of Mines in March 1942. Figures for January and February production are based upon operators' reports of sales of beehive coke.

[4] The Office of Solid Fuels Coordinator for War was changed by Executive order issued April 19, 1943, effective May 4, to Solid Fuels Administration for War.

[1] Daily average production of beehive coke prior to 1941 was calculated by subtracting Sundays and holidays in each month: 1941 and 1942 daily average has been calculated by dividing the total monthly production by the total number of days in the month.

PRODUCTION BY FURNACE AND NONFURNACE PLANTS

Tables 8 and 9 give the production of byproduct coke by plants associated with iron furnaces and by other plants.

The terms "furnace" and "merchant" plants originated in the Connellsville beehive-coke trade. In this report the distinction is applied to byproduct plants only. A "furnace" plant is defined as one that produces, primarily, furnace coke and has an assured outlet for this coke either through financial affiliations with or direct ownership by an iron works or through long-time contracts. The class of "other plants" includes a few plants that are affiliated with local iron furnaces but produce much more coke than the furnaces can absorb and therefore depend chiefly on the foundry and domestic trade or on merchant sales of furnace coke for disposal of the output. The classification of "other plants" also includes merchant producers of furnace coke who sell their entire output on the open market, plants affiliated with alkali works, low-temperature carbonization plants, plants that operate as gas utilities, and a number of plants that, although not public utilities, were constructed primarily to supply city gas and to sell their coke for domestic, industrial, or metallurgical uses. Because of the miscellaneous character of this group of plants, they are not designated as "merchant" but as "nonfurnace" or "other plants." From time to time it may be necessary to change the classification of a given plant because of a change in ownership or market connections.

The activity of "furnace plants" depends principally on the activity of the iron and steel industry, therefore the output of furnace coke follows closely the trend of that industry. In 1942 furnace plants contributed 76 percent of the total byproduct-coke output compared with 77 percent in 1941 and 77 percent in 1940. The relative proportions of "furnace" and "nonfurnace" coke have been remarkably constant during the past 3 years. The relative constancy of this production ratio between the two types of plants illustrates that the demands of industries other than the iron and steel industry affect the market sufficiently for the output of the nonfurnace group to follow, in general, the pattern established by the furnace group.

PRODUCTION BY STATES AND DISTRICTS

The intense activity in the coke industry during 1942 resulted in an increased output in 19 of the 20 States that produced byproduct coke. The average increase for the industry as a whole was 7 percent over the 1941 figure. The only State that did not increase its 1942 output was Indiana, because of the inactivity of 140 ovens at Gary, which were undergoing major repairs. These rebuilt ovens were completed and placed in operation by December 1942.

Pennsylvania led all States in the output of byproduct coke, and its 16,310,167 tons represented 26 percent of the total United States production. This was an increase of 677,813 tons (4 percent) over the output in 1941 and 5,315,913 tons (48 percent) over 1939. The statis-

Digitized by Google

tics of coke production alone fail to do justice to the importance of this State in the coke industry for, in addition to coke, it supplies much of the raw coal required by the byproduct ovens in adjoining States.

Compared with 1941 Alabama led all States in increased tonnage production of byproduct coke, with 819,649 tons, followed by Pennsylvania with 677,813 tons, Ohio with 628,589, and West Virginia with 460,749 tons. The States that showed the largest percentage of increase were Tennessee with 111 percent, Minnesota with 39 percent, West Virginia with 23 percent, and Maryland with 20 percent over the 1941 output.

The production of beehive coke in 1942 was 8,274,035 tons, of which 7,309,337 tons (88 percent) were produced in Pennsylvania; Virginia and West Virginia each contributed 4 percent. All States that produced beehive coke in 1941, except Kentucky, increased their output in 1942. The State showing the greatest increase was Utah, with 119 percent, followed in order by Tennessee 86 percent, West Virginia 28 percent, and Pennsylvania 24 percent.

NUMBER AND TYPE OF OVENS

Byproduct ovens.—At the end of 1942 there were 13,303 byproduct ovens of all types in the United States. This represented an addition of 287 ovens to the 13,016 reported at the end of 1941. The continued expansion of the iron and steel industry at the end of 1942 found the byproduct-coke producers busy replacing old ovens and building new batteries to meet the anticipated needs for metallurgical fuel. At the close of the year, 1,327 new ovens with an annual coke capacity of 6,775,000 tons were reported under construction. The number of byproduct ovens in the United States at the end of 1942, by types, is given in table 14, by States. The majority of the ovens in the byproduct-coke industry are of Koppers and Koppers-Becker types, and of the 13,303 in existence at the end of 1942, 10,263 (77 percent) were of these two types.

Beehive ovens.—The total ovens in existence, as reported by operators, dropped from 18,669 in 1941 to 16,295 in 1942. This change is not significant, however, as operators may consider certain ovens serviceable one year and not serviceable the next, according to general conditions. Some operators do not report any ovens in existence at plants operated by them that are not leased by them from the owners; as plants change management from time to time, different reports are received as to the total ovens in existence at the various plants at various times.

CAPACITY OF BYPRODUCT PLANTS

The potential maximum capacity of the 13,303 byproduct-coke ovens in existence at the end of 1942 was 176,863 tons a day and that of the 1,327 new ovens under construction at the end of the year 18,562 tons a day. Capacity, as thus stated, is defined as the total quantity of coke of the grade the operator aims to produce that can be obtained in a 24-hour period with all conditions favorable and all ovens active. This capacity depends not only on the amount of coal placed in the ovens but on many other factors, including the temperature that can be maintained in the walls of the ovens, which is limited by the character of the refractory materials of these walls; the character and quality of the coal charged; and the width of the oven chamber. Therefore, the potential maximum capacity of the ovens as estimated by the operators is subject to change from year to year according to changes in coking time, coal mixtures, or other variables.

Table 15 shows the relationship between the production of byproduct coke and the potential maximum capacity for each month in 1929 and 1939–42. The operating ratio of the plants has fluctuated with the demand for coke, as noted in the continual rise from 1939, when plants operated at 68.9 percent of the potential maximum capacity, to the all-time high ratio of 96.9 percent in 1942. This figure was 5 percent higher than the hitherto all-time high performance of 1941 and is a credit to the operators, when it is known that more than 50 percent of the ovens in operation in 1942 were more than 20 years old. The 46 furnace plants operated at 97.5 percent and the 42 nonfurnace plants at 95.1 percent of their potential maximum capacity.

[1] Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

QUANTITY AND COST OF COAL CHARGED

The quantity of coal used in the manufacture of coke increased 8 percent in 1942 compared with 1941, but the percentage of the total output of bituminous coal carbonized remained about the same and represented 17 percent of the bituminous-coal production. The total quantity of coal used in making coke in 1942 was 100,849,600 tons, of which 87,973,800 tons (87 percent) were used in byproduct ovens and 12,875,800 tons (13 percent) in beehive ovens.

The average cost of the coal per ton laid down at the ovens was $4.38 for byproduct plants and $2.52 for beehive plants as against $3.92 and $2.33 in 1941. The total cost of coal used in the byproduct and beehive industry in the manufacture of coke was $417,465,208 compared with $348,072,043 in 1941 and represented an increase of 20 percent.

Digitized by Google

However, not all of this figure represented revenue to the coal producers; for most byproduct plants it included the freight rate from mine to ovens. The average cost of coal charged into byproduct ovens in 1942 ranged from $2.92 in West Virginia to $5.64 in Minnesota, where it includes freight rates from distant mines. The average cost of coal for beehive ovens is much less than that for byproduct ovens, as the former are usually built at or near the producing mines and therefore benefit from the savings in transportation charges. West Virginia, with an average cost of $2.18 per ton, was low among the beehive-producing States, and the costs ranged to $3.90 per ton for Colorado and Utah.

The prices of bituminous coal used in making coke in 1942 were governed by Office of Price Administration General Maximum Price Regulation 120, effective May 18, 1942. This regulation was based upon the price of October 1 to 15, 1941, and at the same time took into account the increased costs of production and allowed the producers a somewhat higher price for bituminous coal sold at mines or preparation plants than that during the base period.

PREPARATION AND SOURCE OF COAL

Washed and unwashed.—The preparation of coal used in making coke is very important to many coke producers. Coals available for coke manufacture that contain an undue proportion of ash or sulfur are usually cleaned before being charged into ovens. Both pneumatic cleaning and wet-washing methods are employed. Some coal is cleaned or washed at the mines, and some byproduct-coke plants have washeries adjacent to the ovens. In 1942, 24 coke plants used coal that had been washed at mines, and 7 byproduct-coke plants charged into their ovens coal that was cleaned at the ovens. Table 19 shows the quantity of washed and unwashed coal consumed in the coke ovens of each State. Of the 87,973,821 tons of coal charged into byproduct ovens in 1942, 23,452,747 tons (27 percent) were washed, and in beehive ovens 1,824,619 tons (14 percent) were washed. In Colorado and Tennessee all the coal used for byproduct-coke manufacture in 1942 was washed; also most of that used in Alabama and mined within the State and about half of that used in Pennsylvania.

Sources.—Sources of coking coals have been brought into sharper focus in 1942 because of the close relationship of the coke industry to the iron and steel industry.[5] Pennsylvania and West Virginia are the leading sources of coal used in byproduct-coke manufacture, and these two States supplied more than 75 percent of the bituminous coal so used in 1942. Of the 90,401,393 tons of coking coal purchased by byproduct-coke producers, Pennsylvania supplied 35,636,227 tons (39 percent), followed in order by West Virginia with 32,407,634 tons

Digitized by Google

(36 percent); Kentucky with 10,541,692 tons (12 percent); and Alabama with 7,980,529 tons (9 percent). Other States that supplied appreciable tonnages were Virginia, Colorado, Utah, Illinois, and Tennessee.

Blending coals.—Many operators of byproduct-coke ovens have found that mixing or blending various types of coking coals before charging into ovens will improve the quality of the coke and increase the yield per ton of coal. Operators agree in general that a mixture of low- and high-volatile coals attains this result. However, low-volatile coals with many satisfactory coking qualities expand when coked, and their use alone would cause difficulty in discharging the coke from the oven and injure the byproduct-oven walls. For this reason, it is customary to mix such coals with high-volatile coals, which shrink when coked. This practice also permits the use of coals that have good coking qualities but have objectionable impurities such as high content of ash, sulfur, and phosphorus and for this reason could not be used as 100-percent charge into the ovens to produce coke to conform with specifications upon this basis. Thus, coal mixing, in addition to producing a superior coke, enables the coke industry to utilize coals that in an unmixed condition would not be suitable for coke manufacture.

In 1942, 64 of the 88 active byproduct plants purchased coal of different volatile content. Of these, 40 plants purchased high- and low-volatile coal; 20 plants high-, medium-, and low-volatile; and 4 plants high- and medium-volatile.

Of the 90,401,393 tons of coal purchased, 58,249,586 tons (65 percent) were high-volatile (32 percent and over volatile matter), 19,228,466 tons (21 percent) were low-volatile (14 to 22 percent volatile matter), and 12,923,341 tons (14 percent) were medium-volatile (23 to 31 percent volatile matter).

CONSUMPTION OF COKE

The indicated consumption of coke in the United States in 1942 was 70,107,181 net tons—an 8-percent increase over the 1941 figure. Unusually heavy requirements resulted in the consumption of 54,694,746 tons of furnace coke. This tonnage represented 78 percent of the total requirements; and the remainder—22 percent—was used in foundries, in smelting the nonferrous metals, in the manufacture of water gas, in miscellaneous industries as a chemical reagent, and in domestic heating.

Table 26 shows the coke and coking coal consumed per net ton of pig iron produced in the United States in 1913, 1918, and 1939–42. There was an increase in the 1942 consumption ratio of coke to pig iron, and the coke consumed per ton of pig iron and ferromanganese produced rose from 1,767.8 pounds in 1941 to 1,822.8 pounds in 1942—an increase of 55 pounds (3 percent). Because of this increase, it is indicated that the additional coke required to supply the needs of blast furnaces in 1942 amounted to approximately 1,800,000 tons more than if the furnaces had operated at the 1941 rate of coke consumption per ton of furnace output.

TABLE 25.—*Coke consumed in manufacture of pig iron and for other purposes in the United States, 1913, 1918, and 1939–42, in net tons*

Year	Total production	Imports	Exports	Net change in stocks	Indicated United States consumption [1]	Consumed by iron furnaces [2]		Remainder consumed in other ways	
						Quantity	Percent	Quantity	Percent
1913	46,299,530	101,212	987,395	(3)	45,413,347	37,192,287	81.9	8,221,060	18.1
1918	56,478,372	30,168	1,687,824	(3)	54,820,716	45,703,594	83.4	9,117,122	16.6

FURNACE, FOUNDRY, DOMESTIC, AND OTHER COKE

The terms "furnace coke" and "foundry coke," as used by the trade, refer to size and grade as well as to use. In the manufacture of byproduct coke the facilities for screening or sizing the product permit more precise definitions of grade. In terms of size, byproduct-furnace coke is run-of-oven coke, from which the breeze has been removed. Byproduct-foundry coke is blocky coke of which the maximum size is much greater than that of furnace, and from which all sizes below 2½ to 3 inches have been screened. Domestic coke generally includes a mixture of sizes approximately 3 inches and under, exclusive of breeze. It may result from the screening of foundry and furnace coke; or, where the principal demand is for domestic coke, it may be obtained by crushing the larger fragments. Other special sizes and grades are prepared for special purposes. The majority of the byproduct operators reported that their plants were equipped to screen and size coke for domestic use.

The total quantity of byproduct and beehive coke reported as "used by producers in blast furnaces" and "sold for use in blast furnaces," shown in tables 27 and 28, totaled 55,491,570 tons, whereas the quantity of coke charged into blast furnaces was 54,694,746 tons (table 25), a difference of 796,824 tons. There are two reasons for this discrepancy: (1) Tables 27 and 28 include exports to Canada and other countries, which of course are not included in the record of consumption by American furnaces; (2) tables 27 and 28 cover shipments of blast-furnace coke by producers and do not consider losses due to handling and changes in stocks at blast furnaces.

The total sales of byproduct- and beehive-foundry coke, including exports, were 2,591,576 tons compared with 2,846,459 tons in 1941. The contributing factors that led to decreased use of foundry coke were: (1) Shortages of pig iron and scrap, which diverted coke from cupolas to steel-producing plants; (2) limitation orders which limited the production of cast-iron ware to specified articles and which established quotas for each item of manufacture based upon the amount of iron so used during the year ended June 30, 1941.

The use of both byproduct and beehive coke as a domestic fuel dropped 621,265 tons (9 percent) in 1942 compared with 1941, principally because a number of merchant byproduct-coke plants which had not sold blast-furnace coke in recent years directed some of their output to the iron and steel industry.

[4] Includes 115,265 net tons valued at $691,508 sold for manufacture of water gas.

STOCKS OF COKE AND COKING COAL

Table 29 gives details of the quantity of coke and coke breeze on hand at all beehive and byproduct plants as of January 1, 1943. According to reports from byproduct-coke plants, stocks of furnace and foundry coke totaled 792,072 tons, domestic coke 661,401 tons, and coke breeze 655,175 tons. Stocks of metallurgical coke increased 10 percent during the year, but stocks of domestic coke decreased 33 percent. The decrease in stocks of domestic coke was general at merchant plants in 1942, as many producers were forced to draw from stocks because the current production was directed to the heavy industries.

In the operations of beehive ovens, the output is governed by the sales, and ordinarily stocks are negligible. Producers' stocks of beehive coke totaled 35,576 tons on January 1, 1943. Of this amount, 24,617 tons (69 percent) was blast-furnace coke, 2,203 tons foundry coke, and 8,756 tons domestic coke. Table 30 summarizes total stocks, by grades, at all byproduct and beehive plants as of January 1, 1929, and 1939–43. The stocks of coke on hand at producers' plants

Digitized by Google

by months for 1941 and 1942 are shown in table 31. These data show that stocks of coke carried by furnace plants remained relatively constant, but stocks of coke at merchant plants showed seasonal fluctuations.

Generally stocks of bituminous coal held by byproduct operators closely follow the trend of monthly production. In 1942, however, operators were advised by the Office of Solid Fuels Coordinator for War to build and maintain their stock piles of coking coal to full storage capacity, so that maximum production could be maintained if their normal supply was curtailed. On January 1, 1942, stocks of coking coal at byproduct plants totaled 8,901,462 tons, a 37.7-day supply at the December rate, and they steadily increased until, by December 31, 1942, stocks on hand amounted to 10,721,414 tons, enough for 43.8 days' requirements at the rate of consumption prevailing in December 1942.

VALUE AND PRICE

The term "value" as used in this report means the value of coke at the ovens. For that part of the output sold, the value is the amount received for the coke, f. o. b. ovens. A considerable amount (over

Digitized by Google

63 percent) of the coke produced in the United States is made in ovens operated by large corporations, which not only mine the coal they use for the manufacture of coke but also operate blast furnaces that consume almost all of the output of their ovens. Under such conditions, fixing a value for coal charged and for coke produced is purely arbitrary. With some corporations, the cost of coke to the furnace department equals the cost of production; with others a margin is added, or the cost is considered to be the market price.

The average receipts per ton of coke sold in 1942 increased over those of the previous year because of higher coal costs and increased manufacturing costs. Byproduct- and beehive-coke prices in 1942 were governed by maximum price regulations and are discussed in another section of this report. According to sales data furnished by the operators, average receipts per ton of byproduct coke sold in 1942 increased over the 1941 figures as follows: Furnace coke from $5.23 to $6.06; foundry from $9.76 to $10.15; domestic from $6.96 to $7.88; and other industrial from $6.68 to $7.30. Beehive coke showed the following price increases per ton: Furnace coke increased from $5.47 to $5.64; foundry from $6.49 to $7.05; domestic from $4.94 to $5.54; and other industrial from $5.64 to $6.17.

[1] Coke delivered by trucks to consumers in all States that produced beehive coke.

DISTRIBUTION OF BYPRODUCT AND BEEHIVE COKE IN 1942

The unusually heavy demand for coke in 1942 by various war industries created widespread interest in coke production and distribution data. It is believed therefore that the statistics presented in the following tables showing geographic distribution of coke, by uses, will have interest and value to producers and consumers, and to war agencies responsible for the maintenance of adequate supplies of coke at war plants. The statistical data produced by the survey show (1) coke consumed in each State in 1942 by principal uses and (2) comparable tonnages of coke consumed in each State and region, by uses, from 1940 to 1942. The tonnages shipped to each destination represent

Digitized by Google

approximately the coke consumed therein, and for practical purposes the terms "distribution" and "consumption" are used here interchangeably.

The total consumption of coke in 1942, excluding imports, increased 8 percent from that in 1941 and reached 70,110,497 tons. This rise in consumption was due to the increased activities in the various industries producing essential war material. The tonnage of coke used in blast furnaces increased 5,058,458 tons, but the outstanding development in the distribution of coke in 1942 was the gain in the quantity used for the manufacture of water gas and for miscellaneous industrial purposes, which increased 23 and 27 percent. With the diversion of coke from the domestic trade to the iron and steel industry, the downward trend of domestic consumption that began in 1940 continued through 1942, when coke for domestic use dropped 734,831 tons. The quantity of coke used in foundries dropped 211,559 tons in 1942 compared with 1941, for reasons explained on page 978.

Furnace coke was used in 25 States in 1942. The great centers of consumption were naturally the iron- and steel-producing districts in Pennsylvania, Ohio, Indiana, Illinois, and Alabama, which took 81 percent of the total furnace coke used. Foundry coke was used in all States but 1; coke for the manufacture of water gas in 33 States; and unclassified industrial coke in all but 1 State. The largest tonnages of that classed as "other industrial" were consumed in Pennsylvania, New York, and Michigan. Coke used for domestic heating was distributed to all but 9 States. New York consumed almost one-fifth of the coke used for domestic purposes.

The distribution of coke by uses, by regions, increased in seven of the nine regions as classified (table 37). Outstanding was the increased consumption of 1,909,297 tons (26 percent) in the Southeast region because of an expanded iron and steel industry, chiefly in Alabama and West Virginia. The Middle Atlantic region increased its coke consumption by 7 percent, mainly because of the gain in tonnage of coke used for steelmaking in Pennsylvania. The only regions that showed decreased consumption in 1942 compared with 1941 were the Missouri Valley and the Lake Dock regions. Here decreases resulted from diminished consumption by foundries and for domestic heating.

EXPORTS AND IMPORTS[6]

Exports of coke from the United States totaled 839,582 net tons valued at $6,349,801 in 1942—an increase of 130,611 tons over 1941. The principal export movement of coke in 1941 and 1942 was to Canada, which received 89 percent of all exported coke in 1941 and 96 percent in 1942. Aside from Canada, the export market for American coke is small, although South America received 54,585 tons in 1941 and 18,466 tons in 1942. The increase in exports of coke to South America in 1941 may be traced to World War II. Normally South America received most of its coke for metallurgical purposes from Germany and Great Britain. With those countries at war in 1941, South America turned to the United States for its supply. In 1942 the export movement of coke to South America decreased sharply, both because of increased requirements within the United States and because of shipping difficulties.

Imports of coke supply a very minor part of United States requirements and are a factor in the home market in restricted localities only. In 1941 267,886 tons of coke were imported. Of this amount, Great Britain supplied 178,209 tons (67 percent) and Canada, 89,677 tons (33 percent). In 1942, 108,782 tons were imported, and of this amount 97,386 tons came from Canada and 3,819 tons from Great Britain. In addition, Mexico sent the United States more coke than was exported to it, all of which came through the El Paso and Laredo customs districts. Imports from Canada have remained approximately the same during the past 3 years, although the 97,386 tons received in 1942 exceeded the 1941 figure by 7,709 tons.

WORLD PRODUCTION

The following table shows world production of coke by countries in 1929 and 1939–42 to the limit of available statistics. Because of Government restrictions on the publication of statistics for many of the leading coke-producing countries, few figures have been available since 1939. However, as the output of iron and steel has since increased in most countries, doubtless the production of coke has also increased correspondingly. Production in both Canada and the United States has increased steadily during the past 4 years, and the 1942 output in these countries exceeded all previous production records.

TABLE 41.—*Coke produced in principal countries of the world, 1929 and 1938–42, in metric tons* [1] [2]

[Compiled by B. B. Waldbauer]

Country [3]	1929	1938	1939	1940	1941	1942

[1] Gas-house coke is not included.
[2] In addition to countries listed, coke is produced in Chosen and Japan, but data of production are not available.
[3] Data not available.
[4] January to August, inclusive.
[5] Excluding Sudetenland since October.
[6] In Great Britain the production of gas-house coke (including breeze), not included above, is especially important and was 13,049,139 tons in 1938.
[7] Figures for 1929 represent "hard" and "soft" coke made at collieries only—73,616 tons of "hard" coke and 769,888 tons of "soft" coke. Data for other years shown represent total "hard" coke manufactured. In addition, the following quantities of "soft" coke were made at collieries: 1938, 921,479 tons; 1939, data not available.
[8] Incomplete figure (from coke plants of only 2 mines).
[9] January to July, inclusive.
[10] Exclusive of Mexico.

GAS-HOUSE COKE

The production of gas-house coke in the United States in 1942 totaled 892,552 net tons. The Bureau of Mines obtained data on the manufacture of coke from coal-gas retorts by a survey of this industry conducted at the request of the Office of Solid Fuels Coordinator for War. The survey showed that most of the gas-house

Digitized by Google

coke was sold for domestic heating. Of the 533,882 tons sold, 449,220 tons was for domestic heating, 21,398 tons for water-gas manufacture, and 63,264 tons for miscellaneous industrial uses. The producers used 399,970 tons—206,864 tons for bench fuel, 123,851 tons for water-gas manufacture, 40,708 tons for boiler fuel, and 28,547 tons for the manufacture of producer gas. Table 42 gives salient statistics covering the operations of coal-gas retorts in the United States in 1942.

TABLE 42.—*Salient statistics of the coal-gas industry in 1942 (coke, breeze, and coal figures in net tons)*

	Horizontal retorts	Vertical retorts	Gas ovens	Total
Production:				
Coke	363,358	509,782	19,412	892,552

[1] Includes 15 horizontal gas ovens.

[2] Includes 22 horizontal gas ovens.

COKE-OVEN BYPRODUCTS

SUMMARY OF BYPRODUCTS

Rivaling the coke in importance and in volume of production but more versatile in the forms in which they are used are the byproducts. The volatile matter resulting from the carbonization process is processed to produce the four major byproducts—tar, ammonia, light oil, and gas—by preferential condensation and absorption operations. Initial cooling upon leaving the carbonizing chamber results in the condensation of the heavier higher-boiling-point constituents comprising the coal tar; further cooling with water or scrubbing with sulfuric acid effects recovery of the ammonia as an aqueous solution or in the form of ammonium sulfate; and still further cooling, followed by oil washing, strips out the light oils, consisting mainly of benzol, toluol, xylol, solvent naphtha, and naphthalene. After this point only the gas remains in the system as the final primary product. The further processing of some of the major byproducts involves many chemical industries. Here finished products consist of a host of chemical products, such as dyes, pharmaceuticals, plastics, explosives, and synthetic rubber goods, all of which are indispensable in peace and war.

The acceleration in the rate of coke-oven operation in 1942 increased substantially the production of the byproducts and thereby increased their total sales value. The total sales of all byproducts sold in 1942 (excluding the value of the tar used by the producers and the value of coke breeze produced) increased 11 percent from $158,809,184 in 1941 to $176,932,465 and amounted to 47 percent of the gross value of the coke produced. This was a slight decrease from the 1941 ratio and was caused by the price adjustments of coke and byproducts. The

Digitized by Google

yields of the primary coke byproducts per ton of coal carbonized declined in 1942 from that in 1941 because of more rapid coking rates (fig. 2).

Gas.—Coke-oven gas contributed approximately 50 percent of the total revenue derived from the sales of all byproducts. In addition to providing the fuel requirements of the byproduct ovens from which it is evolved, coke-oven gas supplied other fuel needs. In 1942, 585,455,085 M cubic feet (62 percent) of the 944,879,637 M cubic feet produced were used or sold for industrial purposes and for distribution through city mains. The total value of the gas so used rose from

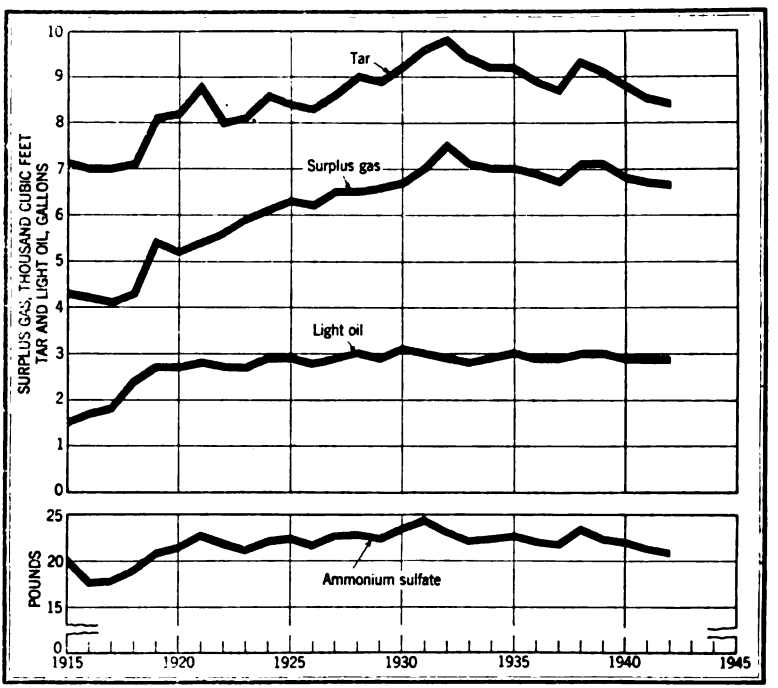

FIGURE 2.—Average yield of principal byproducts per net ton of coal carbonized in byproduct-coke ovens, 1915–42. Figures for light oil represent average at plants recovering light oil.

$85,040,609 to $88,823,807; however, the average sales value as reported by the operators dropped from $0.153 per M cubic feet in 1941 to $0.152 in 1942.

Tar.—The importance of tar as a commercial product has been emphasized during the past year more than ever before. During 1942 the market for tar and its derivatives increased sharply, since the tar derivatives are the basic raw materials from which many products essential to war industries and to public health are made. The diminishing consumption of tar as a fuel in metallurgical works is shown by the increased quantities available each year for refining. The quantity of tar refined by the producers and sold for refining increased 16 percent in 1942 and rose from 458,334,224 to 533,597,898 gallons. In addition, 104,101,925 gallons of crude tar were topped. "Topping" is designed primarily to strip the light oil and tar-acid oil

Digitized by Google

fractions from the crude tar, and in some plants even higher fractions by mild refining. Crude tar, used as fuel by producers and sold for use as fuel, decreased sharply and dropped from 154,065,404 in 1941 to 98,154,832 gallons in 1942. The sales of crude tar in 1942 amounted to 445,597,291 gallons, of which 443,007,596 gallons (99 percent) were sold for refining into tar products and 2,589,695 gallons for fuel. The average unit price of the crude coal tar sold in 1942 rose $0.007 and reached $0.054 per gallon.

Ammonia.—Byproduct-coke ovens are the most important source of fertilizer nitrogen in the United States. The relatively low conversion costs and the large demands for sulfate by the fertilizer industry account for the fact that most of the ammonia recovered from coke ovens is converted to ammonium sulfate. In 1942, 1,533,608,185 pounds of ammonium sulfate and 67,854,384 pounds of ammonia in the form of liquor were produced compared with the 1941 figure of 1,490,395,760 and 62,777,031 pounds. The average unit value of ammonium sulfate remained the same as for the previous year at $0.013 per pound and was governed by Maximum Price Regulation 205.

Light oil and its derivatives.—The primary product, light oil, and its components are extensively used in the chemical industries. The production of crude light oil in 1942 increased 6 percent over 1941 and totaled 246,024,882 gallons. The majority of the byproduct-coke plants have refining equipment adjacent to the ovens, and the light oil is processed on the premises. Of the total production, 241,854,110 gallons (98 percent) were refined by the producers, and only 14,915,409 gallons were sold as crude light oil.

The issuance of War Production Board General Preference Order M–137, effective July 1, 1942, prohibited the use of benzol in motor fuel and placed it under complete allocation. In previous years most of the benzol produced was motor benzol; however, the acute need for industrial pure or 2° benzol by the war industries that manufacture aviation gasoline, synthetic phenol, aniline, and other finished products resulted in issuance of this order. In 1942 the production of motor benzol decreased 40,267,397 gallons, but the production of crude and refined benzol, principally 1° and 2°, increased 46,066,495 gallons. The production of toluol, another major derivative of light oil, advanced from 29,337,178 to 32,314,560 gallons (10 percent), and practically all of it was used for explosives. Toluol had been under allocation since August 1941, following the issuance of the War Production Board General Preference Order M–34 on August 8, 1941.

Naphthalene.—Naphthalene is an important byproduct of coal carbonization. It is solid crystalline hydrocarbon and is obtained principally by cooling coal-tar oils, which boil between 170° and 230° C. Naphthalene is used in the manufacture of phthalic anhydride for smokeless powder, alkyd resins, dyestuffs, perfumes, medicinal insecticides, and moth preventatives. Naphthalene grades are defined in terms of melting points, 79° C. being the dividing line between pure and crude grades. In view of increasing requirements, the byproduct-coke-plant operators increased the output of this valuable byproduct, and production in 1942 rose to 95,612,788 pounds compared with the 1941 figure of 84,046,676 pounds—an increase of 14 percent. The sales of naphthalene increased in proper-

Digitized by Google

tion to the production, and the value totaled $1,941,626—an increase of $419,108 (28 percent). Naphthalene was placed under allocation on May 6, 1942, following issuance of the War Production Board General Preference Order M–105.

1942	95,039,639	1,941,626	2.0	3.1

BYPRODUCT-COKE OVENS OWNED BY CITY GAS COMPANIES (PUBLIC UTILITY PLANTS)

The adaptability of byproduct ovens to the needs of city gas manufacture has led a number of gas companies to install batteries of byproduct ovens to supplement or even replace coal- or water-gas sets. Although more emphasis is placed upon the production of gas of proper analysis than upon the grade of coke obtained, viewed from supply and demand for coke and byproducts, these installations belong to the byproduct-coke industry and are therefore included in the current statistics compiled by the Bureau of Mines and released to the public

Digitized by Google

in weekly and monthly reports. The difference in classification is maintained in the interest of those who may want to obtain information on the operations of city gas works proper. Table 52 shows separate figures for the group of byproduct-coke plants operated by city gas companies (Public Utilities) and for all other byproduct-coke plants. In 1942, there were 16 active plants in the group owned by city gas companies and they produced 3,693,407 tons of coke, 59,480,526 M cubic feet of gas, 48,548,754 gallons of tar, and 7,973,417 gallons of light oil. This was an increase of 9 percent for coke, 6 percent for gas, 6 percent for tar, and 28 percent for light oil. This table also shows the operations of the plants not owned by city gas companies, which in 1942 produced 58,601,502 tons of coke, 885,399,111 M cubic feet of gas, 691,626,865 gallons of tar, and 238,051,465 gallons of crude light oil.

SUMMARY

Notwithstanding difficulties resulting from the war in securing raw fuel, labor, and miscellaneous supplies and the increase in manufacturing cost, production in the briquet industry reached an all-time high of 1,748,300 net tons in 1942—a 35-percent increase over 1941, the former record year; the output of packaged fuel (considered separately in this report) amounted to 253,048 net tons—a decrease of 6 percent compared with 1941. The combined output totaled 2,001,348 tons, valued at $13,806,128.

Statistics on fuel briquets have been collected since 1907, when 11 plants produced a total of 66,524 net tons. Data on packaged fuel have been collected since 1935, and for the 5 years following the industry made a remarkable record of growth, attaining the peak production of 284,513 tons in 1940—more than 11 times that produced in 1935. In 1941 and 1942 production declined.

As during World War I, the scarcity of competing fuels created a very large demand in 1942 for briquets for domestic use; the trend toward utilization of fireplaces as an added source of heat has brought briquets and packaged fuel into greater service.[2] Despite the heavy demand for these fuels, the industries, especially the packaged-fuel industry, have suffered from inability to obtain the raw materials of manufacture, labor, and necessary repair parts, as well as from the increased cost of these items, which forced many plants to discontinue operation for the war, some permanently. No sales of bri-

[1] Directories of fuel-briquetting and packaged-fuel plants operating in 1942 will be furnished, on request, by the Coal Economics Division, Bureau of Mines, Washington, D. C. Names of manufacturers of equipment will not be issued for 1942, as companies formerly listed therein did not manufacture fuel-briquetting machinery in 1942 owing to pressure of war work.

Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Data on employment and the principal expenses in the manufacture of fuel briquets may be obtained from the Bureau of the Census, which collects and publishes such data in alternate years; 1939 is the latest year for which such data have been collected.

Briquets made from charcoal, wood wastes, and fruit pits are not included in the Bureau of Mines review.

quetting or packaged-fuel equipment were reported for 1942 by the manufacturers of such machinery because of priorities, but a number indicated the diversion of their business to war work.

In an effort to meet urgent fuel needs, various briquetting projects have been advanced in foreign countries. Inquiries from Argentina concerning the possibilities of briquetting surpluses of corn and corn husks have resulted in the construction of a plant for the manufacture of corn briquets for domestic and industrial fuel uses, and American machinery has recently been installed at the Brazeau Collieries, Ltd., in Canada, for producing binderless briquets from coal fines.[3]

Technologic developments.—The briquetting and packaged-fuel industries continued their research in 1942, although a number of projects were laid aside in favor of work of a military nature.

A technologic and economic study of the packaged-fuel industry, which began in the fall of 1941 by V. F. Parry of the Fuels and Explosives Service, Bureau of Mines, Golden, Colo., has been completed and it is expected that the results will be published during 1943.[4] A study has been completed by V. F. Parry and J. B. Goodman [5] of the Bureau of Mines laboratory in Golden, Colo., dealing with the technical phases of the briquetting industry.

Construction of the commercial-scale briquetting press designed by R. J. Piersol [6] at the Illinois State Geological Survey was completed in 1941, but owing to delays in obtaining the necessary equipment because of war priorities the date for final demonstrations on briquetting various Illinois coals scheduled for 1942 has been postponed further.

Komarek-Greaves & Co.[7] of Chicago, Ill., is reported to have developed a roll press for manufacturing fairly strong briquets from low-volatile coals without a binder, using pressures of 30,000 to 40,000 pounds per square inch. Three of these presses are operating in Canada.

FUEL BRIQUETS

Salient statistics of the fuel-briquetting industry from 1938 to 1942 are summarized in the following table. Detailed data for earlier years, beginning with 1907, are to be found in annual issues of Mineral Resources (part II) and Minerals Yearbook, which include chapters on briquetting. Production and value from 1915 to 1942, inclusive, are presented graphically in figure 1.

Production.—The output of fuel briquets in 1942—1,748,300 net tons valued at $11,266,041—represents an increase of 35 percent in tonnage and 41 percent in value over 1941, the previous record production year. This increase in production in 1942 is readily explained by the general increase in demand for fuels of all kinds in time of war.[8] The present full rated capacity of the industry is nearly double the 1942 production.

Briquets were produced in 14 States, and all but 3 showed increases over 1941. Almost half of the output came from Wisconsin, where production increased 40 percent over 1941; West Virginia, Pennsylvania, and Missouri followed in order, with large increases in production. In Missouri three plants, two of which were new in 1942, produced a total of 104,415 tons valued at $589,466. Output for the 12 States (other than Wisconsin and Missouri) that produced briquets in 1942 cannot be shown separately without revealing individual data. The large quantities of bituminous slack available at Lake ports, resulting from rehandling of coal at the docks, have helped to make Wisconsin the leading State in production of fuel briquets.

Production of fuel briquets in the United States, 1941–42

	1941			1942				
	Plants	Net tons	Value	Plants	Net tons	Value	Percent of increase over 1941 in—

[1] 1941: 10 plants in Wisconsin; 2 each in California, Illinois, Michigan, Nebraska, Washington, and West Virginia; and 1 each in Arkansas, Massachusetts, Minnesota, Missouri, North Dakota, Ohio, Oregon, Pennsylvania, Texas, and Wyoming; 1942: 10 plants in Wisconsin; 3 in Missouri; 2 each in California, Illinois, Michigan, Nebraska, and West Virginia; and 1 each in Arkansas, Minnesota, North Dakota, Oregon, Pennsylvania, Washington, and Wyoming.

Production of fuel briquets in Wisconsin, 1937–42

Year	Plants	Net tons	Value	Year	Plants	Net tons	Value
1937	10	507,462	$3,639,183	1940	11	487,574	$3,440,676
1938	10	422,281	3,085,873	1941	10	535,457	3,870,077
1939	10	430,554	3,158,859	1942	10	750,417	5,498,748

Other large plants are located at coal mines, chiefly in West Virginia and Pennsylvania, and smaller operations at gas plants and petroleum refineries, principally in the Pacific Coast States.

Nearly 51,000 net tons of bulk briquets were packaged at producing plants by 13 operators. No data are available on the quantity of briquets packaged by retailers.

As briquets are used mostly for domestic space heating, production normally is highly seasonal. However, in 1942 wartime demands resulted in more uniform production than in previous years. Twenty-

[8] Black Diamond, Twin Cities and Northwest: Vol. 109, No. 9, 1942, p. 48; Kansas City News Notes: Vol. 109, No. 12, 1942, p. 57.

Digitized by Google

three of the 30 active plants were operated every month of the year, and only 2 less than 6 months—1 of these was a new company that began operations in October.

In 1942, production was lowest in March, but in May it stepped up markedly. According to the Weather Bureau,[9] below-normal temperatures prevailed during May in the North Central States, where the bulk of briquet consumption is concentrated. The unusual jump in production for October, when above-normal warmth prevailed, can be explained no doubt by the anticipated heavy seasonal demands because of a threatened scarcity of competing fuels.

Monthly production of fuel briquets in the United States, 1940–42, in net tons

Month	1940	1941	1942	Month	1940	1941	1942
January	157,091	135,532	170,991	August	58,706	109,487	112,434
February	76,550	118,596	122,083	September	84,466	107,257	139,699
March	68,981	85,728	93,668	October	92,295	120,197	204,665
April	43,936	27,252	102,514	November	128,301	143,330	177,938
May	66,449	82,723	145,792	December	140,133	137,166	197,982
June	57,814	105,307	146,389				
July	76,148	126,022	134,145		1,050,870	1,298,606	1,748,300

Value.—Sales realizations on briquets vary considerably in the widely separated producing centers in a given year, therefore an average value per ton for the entire industry has little significance because conditions under which briquets are manufactured and sold differ throughout the country. The most important factors that influence the value per ton realized at any plant are the cost of raw materials, labor, and price of competing fuels; hence, the trend of fuel-briquet prices in the past 5 years is indicated best in this review by considering the average values in the Eastern, Central, and Pacific Coast States separately, as shown in the last three columns of the salient statistics table. These figures are the values received by producers for the total product (exclusive of delivery charges) and not the prices paid by consumers. Some plants are far from the markets they serve, and transportation charges and the margin of the wholesaler or retailer—sometimes both—must be added to the value at the plant.

The total value of fuel briquets manufactured in 1942 was $11,266,041 f. o. b. plant, an increase of $3,264,212 (41 percent) over 1941. This large increase is due to a great extent to the 35-percent increase in production.

In the eastern part of the United States the average value ($4.56 per ton) was relatively low because all the output came from plants in the low-volatile bituminous fields of West Virginia and in the anthracite region of Pennsylvania, where freight charges are a small proportion of the cost of raw fuel. In the Central States, where the average value was $7.04 per ton, the major part of the production comes from the docks at Lakes Michigan and Superior, and the cost of raw fuel at these plants involves a considerable freight charge. In the Pacific Coast States, where residual carbon from the manufacture of oil gas constitutes the greater part of the raw fuel used, the average value increased from $8.36 in 1941 to $9.69 in 1942.

[5] Price per ton of 2,240 pounds.
[6] Not comparable with preceding months.

Number of plants.—Records show 30 plants in commercial operation in 1942; all but 2 of these (the new briquetting plant of the Smokeless Coal Blox Co.[10] and that of the St. Louis Briquette Co., Inc., both at St. Louis) were also active in 1941. One plant active in 1941 failed to report operations for 1942. Nine plants were idle in 1942; of these, 6 were also idle in 1941, and 3 went out of business. Of the 2 reported as under construction in 1941 to begin operations in 1942, 1—

[10] Black Diamond, St. Louis News Notes: Vol. 107, No. 11, 1941, p. 43.

Digitized by Google

the Smokeless Coal Blox Co., at St. Louis—went into commercial production in 1942. In 1942 the Binkley Coal Co. purchased the Standard Briquet Fuel Co. plant at Kansas City, which it had been operating as lessee since 1935.

Size of plants.—The following table classifies the plants operating in 1941 and 1942 according to actual production as well as rated capacity. Rated capacity, of course, is the better indicator of the relative size of plants.

The total annual rated capacity of the 30 plants active in 1942, as shown on operators' reports, was over 3 million net tons. It should be noted that, notwithstanding the great increase in production over 1941, these 30 plants could nearly double their 1942 output should demand warrant.

The average output of individual plants increased from 41,000 tons in 1941 to 58,000 in 1942 (41 percent). Twenty-three plants operated every month and produced 1,709,997 tons or about 98 percent of the total.

Classification of briquetting plants in the United States, 1941–42, by size of output and annual capacity

Output (net tons)	Plants		Annual capacity (net tons)	Plants	
	1941	1942		1941	1942
Less than 2,000	6	2	Less than 5,000	2	1
2,000 and less than 5,000	2	3	5,000 and less than 10,000	4	2
5,000 and less than 10,000	3	5	10,000 and less than 25,000	6	7
10,000 and less than 25,000	9	5	25,000 and less than 100,000	11	9
25,000 and less than 100,000	6	9	100,000 and less than 200,000	5	7
100,000 and over	6	6	200,000 and less than 400,000	2	2
			400,000 and over	2	2
	32	30		32	30

Raw fuels.—The number of plants, classified according to type of fuel used in 1942, was as follows:

Classification of fuel-briquetting plants in the United States in 1942, by kinds of raw fuel used

Kind of raw fuel used:	*Plants*
Anthracite and semianthracite fines exclusively	6
Mixture of Pennsylvania anthracite and bituminous	4
Bituminous:	
Low-volatile	14
High-volatile	2
Semicoke (lignite char)	1
Residual carbon from pyrolysis of natural gas	1
Residual carbon from manufacture of oil gas	2
Petroleum coke	6
	[1] 36

[1] 4 plants made 2 kinds and 2 plants 3 kinds of briquets; hence, the sum of the items exceeds the total number of plants.

It is noteworthy that in 1942 the production of fuel briquets from petroleum coke, which in recent years had been used in increased amounts, dropped far below the 1941 figure. Large quantities of petroleum coke are now used for manufacturing ashless carbon electrodes essential in producing aluminum and other metals by electrometallurgical processes.

A small tonnage of raw Texas lignite was made into briquets in 1940

Digitized by Google

and 1941, but no briquets were produced from such raw material in 1942, owing to the labor shortage and the general effect of the war on small industries. In 1942 six operations reported making more than one kind of briquet—four plants made two kinds and two plants made three kinds. Six operators reported washing a total of 349,100 tons of raw fuel before using it in the manufacture of briquets.

Raw fuels used in making fuel briquets in the United States, 1941–42

Raw fuel	Net tons		Percent of tota	
	1941	1942	1941	1942
Anthracite and semianthracite culm and fine sizes	265,637	386,947	21.6	23.4
Bituminous and subbituminous slack	[1] 787,722	1,077,474	64.1	65.3
Residual carbons from oil-gas manufacture and natural-gas pyrolysis; petroleum coke; and semicoke (lignite char)	175,043	187,207	14.3	11.3
	1,228,402	1,651,628	100.0	100.0

[1] Includes small tonnage of Texas lignite used without charring.

Production of fuel briquets, 1941–42, grouped according to location of plants with reference to supply of raw fuel

Location of plant	Net tons		Percent of change in 1942
	1941	1942	
At or near Lake Superior or Lake Michigan coal docks	560,506	782,436	+39.6
At coal mines	579,844	789,535	+36.2
At or near petroleum refineries and oil- and natural-gas plants	142,378	163,294	+14.7
At other locations [1]	15,878	13,035	−17.9
	1,298,606	1,748,300	+34.6

[1] Jackson, Mich., and Omaha, Nebr.

Binders.—The following table classifies the fuel-briquet plants by type and percentage of binder used. As indicated in the table, asphaltic pitch continues to be the preferred binder in briquetting coal and coke. Approximately 102,000 tons of asphaltic pitch and smaller amounts of other binders were used in 1942 in the manufacture of fuel briquets.

In 1942, as in 1941, three plants used no binder; two of these briquetted the carbon residue from the manufacture of oil gas, and one used low-volatile bituminous coal.

Classification of briquetting plants in the United States in 1942, by type and percentage of binder used

Type of binder	Plants	Production		Ratio of binder to raw fuel (by weight)	Plants	Production	
		Net tons	Percent of total			Net tons	Percent of total
Asphaltic pitch	22	1,390,481	79.5	Less than 5 percent	4	197,236	11.3
Mixed pitches	1	239,092	13.7	5 and less than 7 percent	12	548,834	31.4
Asphalt and starch	2			7 and less than 9 percent	9	883,503	50.5
Starch	2			9 percent and over	2		
No binder	[1] 3	118,727	6.8	No binder	[1] 3	118,727	6.8
	30	1,748,300	100.0		30	1,748,300	100.0

[1] 2 plants use residual carbon from manufacture of oil gas and 1 uses bituminous coal as raw fuel.

Weight and shape.—Pillow-shaped briquets continue to be the most popular in the United States. Of the 30 active plants in 1942, 24 produced 1,250,360 tons (72 percent) of this type briquet, 4 plants 19,034 tons (about 1 percent) of cube-shaped briquets, and 3 plants 478,906 tons (27 percent) of the cylindrical type. One of these made both pillow- and cube-shaped briquets; hence, the sum of the plants described above exceeds by 1 the total number of active plants. Records show two plants making briquets in 1942 in more than one shape and three plants making two sizes.

Prevailing weight of briquets produced in the United States in 1942

Weight (ounces)	Plants	Production		Weight (ounces)	Plants	Production	
		Net tons	Percent of total			Net tons	Percent of total
Less than 2	3	45,757	2.6	6 and under 10			
2 and under 3	11	926,975	53.0	10 and under 16	1	76,431	4.4
3 and under 4	7	536,565	30.7	16 and under 25	4		
4 and under 5	5	162,572	9.3				
5 and under 6					[1] 31	1,748,300	100.0

[1] 1 plant made a 2-ounce pillow briquet and a 24-ounce cube; hence, the sum of these items exceeds the total number of plants.

Distribution.—According to reports received, shipments of briquets during 1942 increased 27 percent over 1941; they were shipped into 37 States and the District of Columbia and exported to other countries.[11]

It is not possible to show shipments from each producing State because there are only one or two producers in each of the States except Missouri and Wisconsin, and confidential reports of individual companies would thus be revealed. However, for a graphic presentation of the centers of production for 1928 and 1936, with corresponding States of destination, see Minerals Yearbook, 1937 (p. 965, fig. 65).

Generally, rail shipments represent consumption at distant points, and shipments by truck show local and nearby consumption.

Shipments of fuel briquets of domestic manufacture, 1941–42, by States of destination, as reported by producers, in net tons

State	1941	1942	State	1941	1942

[1] Includes shipments outside the United States.
[2] Includes local deliveries.

Imports and exports.—Before 1922 the quantity of fuel briquets imported into the United States was negligible. The anthracite shortages of 1922–23 and 1925–26, however, created a demand for the European product (mostly from Germany, Belgium, and France, and mainly for consumption in the anthracite-consuming States), which in 1926 reached a peak of 123,593 net tons. Imports continued at a comparatively high level through 1932, when they totaled 80,288 tons. Thereafter they dropped sharply and since September 1939—the beginning of the war—have virtually ceased. In 1941, 162 tons were imported from Canada; and in 1942, 325 tons came from Canada and 9 tons from the United Kingdom.

Figures for imports of briquets since 1919 (the first year of record) are included in annual volumes of Mineral Resources and Minerals Yearbook.[12]

Briquets (coal and coke) and other composition coals for fuels imported for consumption in the United States, 1938–42

Year	Net tons	Value	Year	Net tons	Value
1938	13,814	$67,366	1941	162	$791
1939	1,344	5,752	1942	334	1,739
1940					

Wartime fuel demands are reflected in briquet-export data. Canadian shipments in 1942 amounted to 103,329 net tons, more than three times the 1941 tonnage. Canada received 77 percent of the total exports in 1941 and 99.5 percent in 1942.

Briquets (coal and coke) exported from the United States, 1941–42, by countries and customs districts

World production.—Official data on production of fuel briquets in other countries since 1939 have been meager, owing to the war.

World production of fuel briquets, 1937–42, by countries, in metric tons [1]

[1] In addition to countries listed, briquets are produced in Canada and New Caledonia, but data on output are not available.
[2] Data not available.
[3] Data for year ended March 31 of year stated.
[4] January to June, inclusive.
[5] Includes packaged fuel as follows—1937: 132,482 tons; 1938: 146,012 tons; 1939: 195,504 tons; 1940: 258,105 tons; 1941: 244,797 tons; 1942: 229,560 tons.
[6] Totals incomplete; they represent sum of figures given in table only.

PACKAGED FUEL

Packaged fuel differs from fuel briquets in that the former is made up of more or less friable rectangular blocks wrapped together to form neat, tightly fitted packages, which withstand weathering fairly well, eliminate much of the breakage, and provide a relatively clean fuel to handle. They are designed primarily for local or nearby consumption. The packages, wrapped in heavy paper and sealed with gummed tape, usually consist of 3- to 4-inch cubes (six or eight to a package, the package weighing 10 to 15 pounds). Packaged fuel is made from various types of coal or coke screenings, usually mixed with a neutral binder. Its growth in popularity has been due largely to its convenience and cleanliness in handling and to the fact that it may be purchased in less-than-ton lots.

Production of packaged fuel declined in 1942. The phenomenal growth of this industry from 1935 through 1940 is illustrated strikingly in figure 2. In 1941, however, production dropped 5 percent from 1940; and in 1942, it dropped 6 percent from 1941. World War II and competition within the industry are the major factors for the decline since 1940.

The effect of the war on this industry has been felt mostly through increased cost of raw fuels, manufacturing materials, and labor as

Digitized by Google

well as the inability to obtain the same. According to operators' reports, the cost of production in 1942 increased to such an extent that it has made the price of packaged fuel prohibitive and has forced a large number of plants to discontinue operations for the war, some permanently.

Machinery manufacturers reported no sales for fuel-briquetting or packaged-fuel installations in 1942, principally because of priorities on the necessary materials; a number of them have followed the war trend and diverted their businesses to war work—one manufactured special machinery for briquetting iron ore and flue dust [13] and another a press to be used in research work on the briquetting of sponge iron.

Processes.—United States operators in 1942 reported no new processes or types of machinery for use in the packaged-fuel industry. The Eberling process [14] was used by 75 manufacturers in 1942. Other processes used were the Glenn-Smith [15] and Leemon [16]; and one manufacturer—the Johnson Coal Cubing Co.,[17] of Detroit, Mich., largest operator since 1932—uses a process and equipment of its own design. The process and machine developed in 1939 by the Viking Manufacturing Co., of Jackson, Mich., are not yet in use in the United States, but plans are under way for a number of such installations after the war. These processes are discussed in earlier reports of this series and in the trade journals.

Salient statistics of the packaged-fuel industry from 1937 to 1942 are summarized in the following table; 1935 was the first year for which such data were collected by the Bureau of Mines.

Salient statistics of the packaged-fuel industry in the United States, 1937–42

[Data regarding fuel briquets are given separately at beginning of this chapter]

Year	Production (thousands of net tons)			Value of production (thousands of dollars)	Plants in operation	Average output per plant (thousands of net tons)	Average value per net ton, f. o. b. plant	
	Eastern and Pacific Coast States	Central States	Total				Eastern and Pacific Coast States	Central States
1937	10	136	146	1,287	64	2	$9.62	$8.76
1938	9	152	161	1,405	76	2	9.92	8.66
1939	9	207	216	1,867	103	2	9.69	8.62
1940	8	277	285	2,392	106	3	10.12	8.36
1941	10	260	270	2,472	103	3	10.95	9.09
1942	8	245	253	2,540	89	3	10.74	10.02

Production and value.—The 89 active plants in 1942 produced 253,048 net tons with a value of $2,540,087 (see fig. 2); all but 7 of these plants are in the Central States. Production decreased 6 percent from 1941, but the total value increased 3 percent.

Output declined in 8 of the 13 States producing packaged fuel; of the three largest producing States—Michigan, Ohio, and Wisconsin, in order named—only one (Wisconsin) showed an increase in production over 1941.

Total Central States	96	260,295	2,366,963	82	245,465	2,458,678
Eastern and Pacific Coast States	[3] 7	9,549	104,604	[3] 7	7,583	81,409
Total United States	103	269,844	2,471,567	89	253,048	2,540,087

[1] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[2] Includes States entered as "1" above.
[3] Maine 2, Pennsylvania 1, Virginia 3, and Washington 1.

The values, by States, in the following table represent the average per ton received by operators in 1941 and 1942 and indicate increases in average realization in each of the eight States shown; similar advances were prevalent in all but one of the other producing States, but these cannot be shown because there were less than three operators

Digitized by Google

in each State. The values do not represent the price per ton to the consumer, as many plants sell both to retailers and consumers, but rather the average per ton received by producers on the total product (exclusive of delivery charges). The value at the plant comprises cost of coal at the mine, freight rate, direct and indirect manufacturing costs, and profit.

Average value received per net ton of packaged fuel, 1941–42

State	1941	1942	State	1941	1942
Illinois	$10.69	$12.05	Missouri	$8.19	$8.49
Indiana	9.06	10.11	Ohio	9.23	10.10
Michigan	8.54	9.74	Virginia	9.70	10.06
Minnesota	10.82	11.45	Wisconsin	9.15	9.67

Only about one-fifth of the plants in preceding years were active throughout the year, but 42 of the 89 plants active in 1942 operated each month of the year, and only 9 plants operated less than 6 months.

Monthly production of packaged fuel in the United States, 1941–42, in net tons

Month	1941	1942	Month	1941	1942
January	39,594	33,924	August	10,184	9,346
February	37,727	29,360	September	17,422	18,519
March	40,893	26,779	October	27,183	30,378
April	17,592	19,353	November	30,506	26,361
May	6,318	14,068	December	30,296	27,739
June	5,028	9,533			
July	7,101	7,688		269,844	253,048

Number of plants.—Eighty-nine plants reported commercial production of packaged fuel in 1942; 85 of these were also active in 1941. There were four new plants in 1942; three of these reported production. One plant in Indiana, new in 1941, started operating in 1942. Eight plants went out of business in 1942; five of these had been in operation part of the year, and three were plants that had been in operation each year for 8 years or more. From 1935 to 1940—the peak year—many plants established themselves firmly and built up a stable business; but during this development period a relatively large number of plants went out of business soon after they began to operate.

Activity in number of packaged-fuel plants, 1937–42

Year	Active	New	Idle	Out of business	Year	Active	New	Idle	Out of business
1937	64	17	6	3	1940	106	16	15	14
1938	76	16	8	1	1941	103	7	8	14
1939	103	29	11	9	1942	89	[1] 4	[2] 16	[3] 8

[1] 2 in Michigan and 2 in Ohio; all but 1 active in 1942.
[2] 8 in Michigan, 3 in Ohio, 2 in Wisconsin, and 1 each in Idaho, Minnesota, and Missouri; 5 of these also idle in 1941.
[3] 4 in Michigan, 2 in Ohio, and 1 each in Missouri and Idaho; 7 of these active in 1941.

Size of plants.—The average annual production per plant increased from 2,600 tons in 1941 to 2,800 in 1942. According to operators' reports the industry, if operated at full capacity, could produce 2½ times its 1942 output.

Digitized by Google

Classification of packaged-fuel plants in the United States, 1941–42, by size of output and annual capacity

Output (net tons)	Plants		Annual capacity (net tons)	Plants	
	1941	1942		1941	1942
Less than 500	[1] 25	[2] 20	Less than 5,000	68	52
500 and less than 1,000	19	14	5,000 and less than 10,000	17	21
1,000 and less than 3,000	39	38	10,000 and less than 15,000	6	5
3,000 and less than 5,000	5	6	15,000 and less than 25,000	6	6
5,000 and less than 10,000	9	7	25,000 and less than 40,000	5	4
10,000 and less than 25,000	5	3	40,000 and less than 60,000		
25,000 and over	1	1	60,000 and over	1	1
	103	89		103	89

[1] 2 of these began operations in the fall of 1941. [2] 1 of these began operations in the fall of 1942.

Raw fuels.—The kinds and quantities of raw fuels used are shown in the following table. The decrease in petroleum coke (which rose significantly from 1939 to 1941) is due to the War Production Board freeze order on this fuel, which became effective in October 1942.[18]

Low-volatile bituminous cubes were made at 77 plants in 1942, petroleum-coke cubes at 10, high-volatile bituminous cubes at 3, and semianthracite cubes at 2; cubes of mixtures of the various raw fuels were made at 2 plants. Five operators made more than one kind, and three made cubes in two sizes. About 188,000 tons (75 percent) of the total raw fuels were shipped-in slack from the mines and Lake docks; the remainder represents yard screenings. Proportionately fewer operators used shipped-in slack exclusively in 1942 than in 1941—owing to difficulties in obtaining the raw fuels.

Raw fuels used in making packaged fuel in the United States, 1941–42

Raw fuel	Net tons		Percent of total	
	1941	1942	1941	1942
Bituminous (high-volatile) and semianthracite	4,784	8,053	1.8	3.2
Bituminous (low-volatile)	213,474	210,761	80.0	84.2
Petroleum coke	[1] 48,560	31,571	18.2	12.6
	266,818	250,385	100.0	100.0

[1] Includes small tonnage of coke breeze.

Binders.—Cornstarches of various types, averaging about 15 pounds per ton of packaged fuel produced, continue to be the principal binders used in the manufacture of packaged fuel. Cement and asphalt—either alone or in combination with starch—were also employed. About 1,600 tons each of starch and asphalt and 83 tons of cement were used by packaged-fuel operators in 1942. The following table classifies the packaged-fuel plants in 1941 and 1942 according to type and percentage of binder used.

Classification of packaged-fuel plants in the United States, 1941–42, by type and percentage of binder used

Type of binder	Plants		Ratio of binder to raw fuel (by weight)	Plants	
	1941	1942		1941	1942
Starch	91	82	Less than 0.5 percent		
Starch and cement	3	2	0.5 and less than 1 percent	71	65
Starch and asphalt	1	1	1 and less than 2 percent	26	19
Cement	5	2	2 and less than 3 percent	4	1
Asphalt	2	2	3 and less than 5 percent		2
Sulfite cellulose	1		5 percent and over	2	2

PEAT

By Joseph A. Corgan

SUMMARY OUTLINE

	Page		Page
Summary	1021	Uses	1023
Reserves	1021	Imports	1023
Production	1021	World production	1024

SUMMARY

Reports received by the Bureau of Mines from producers indicate that the output of peat in the United States in 1942 totaled 71,500 short tons valued at $516,887—substantially less than in 1941, when the production was 86,503 tons valued at $657,556. The decline can be attributed largely to cessation or curtailment of operations at many peat bogs because of a shortage of labor. In 1942 imports amounted to 49,236 short tons valued at $1,219,473, an increase over 1941 of 62 percent in quantity and 73 percent in value. Although the quantity imported in 1942 was considerably below the pre-war figure of 78,611 tons in 1939, the reported value of $1,219,473 in 1942 was slightly higher than that in 1939 No exports were reported for 1942; thus, the total quantity available for domestic consumption (domestic production plus imports) was 120,736 tons, a gain of 3,891 tons over 1941 but a decline of 13,358 tons from 1939. In the United States, peat is used primarily for soil improvement and in mixed fertilizers. As in many years past, producers reporting for 1942 showed no use of peat as fuel.

Every effort has been made to cover in the canvass all commercial operations. A directory, listing names and addresses of operators who reported production in 1942 to the Bureau of Mines, has been prepared; it will be sent, upon request, to those who may be interested.

Reserves.—The peat reserves of the United States are extensive and constitute an important item in the natural resources of the country. About half of the States contain some peat reserves. The total, calculated as air-dried peat, has been estimated to be 13,827,000,000 tons. [1] Three of the Great Lakes States—Minnesota, Wisconsin, and Michigan—together contain 75 percent of the reserves, and 14 percent of the country's total is in Florida; in the Pacific Coast region, California contains most of the known deposits.

PRODUCTION

Commercial production of peat in the United States was reported to the Bureau of Mines by 41 producers operating in 17 States in 1942, compared with 49 producers in 17 States in 1941. The decline in output from 86,503 short tons in 1941 to 71,500 tons in 1942 and the decrease of 8 in number of producers were caused primarily by the

[1] Soper, E. K., and Osbon, C. C., The Occurrence and Uses of Peat in the United States: Geol. Survey Bull. 728, 1922, p. 92.

Digitized by Google

closing of some plants for the duration of the war and a shortage of labor at others. Some of the operators indicated that former employees are in the armed forces and that the plants will not reopen until the war is over.

The average value of peat per ton was $7.23 in 1942, compared with $7.60 in 1941. Production and value for the years 1937 to 1942 are shown in the following table.

Peat produced in the United States, 1937–42

Year	Short tons	Value	Year	Short tons	Value
1937	51,223	$305,156	1940	70,097	$516,865
1938	45,933	286,127	1941	86,503	657,556
1939	55,483	362,066	1942	71,500	516,887

Figure 1 illustrates graphically the trend in production and value of peat from 1908 to 1926 and 1934 to 1942. The Federal Government made no canvass of the industry from 1927 to 1933, inclusive, and no data for these years are available.

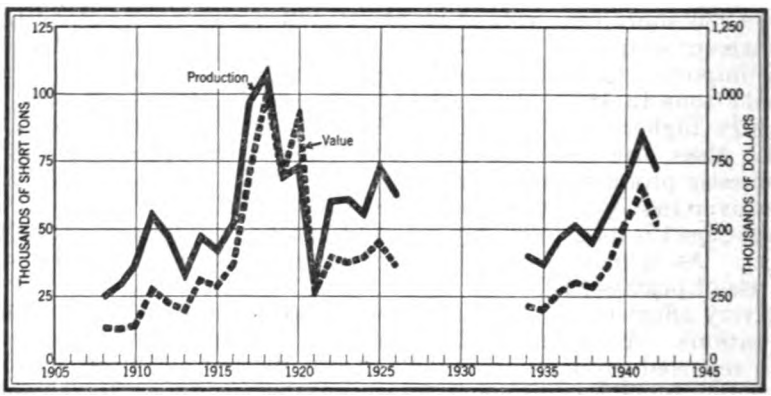

FIGURE 1.—Quantity and value of peat production, 1908–42; no data available for 1927–33.

In 1942 the producing States, in order of output, were: Illinois, New York, Michigan, New Jersey, Iowa, Maine, Pennsylvania, California, Minnesota, Florida, Wisconsin, Connecticut, Ohio, Georgia, Massachusetts, Washington, and New Hampshire. In 1941 New York led in output and was followed by Illinois, New Jersey, and Michigan; the order of the other States also varied from that in 1942.

Peat humus comprised 53 percent of the total production in 1942; reed or sedge peat, 31 percent; and moss peat and other, 16 percent. Peat humus was produced in 9 States, reed or sedge peat in 8, and moss peat in 7.

One plant reported production of kiln-dried peat; 12, raw peat; 14, shredded peat; and 8, cultivated peat.

Digitized by Google

USES

Peat is used for soil improvement on lawns, golf courses, and gardens, and at greenhouses and nurseries; as packing material for plants, shrubs, eggs, fruits, vegetables, and fragile articles; for insulating material; and as litter for livestock and poultry. The principal use of peat in the United States is in agriculture and horticulture as a soil conditioner and an ingredient of fertilizer. In 1942, of the total peat sales 61 percent was used for soil improvement, 30 percent in mixed fertilizers, and 9 percent for other purposes. No sales of peat for fuel in 1942 were reported, although in some European countries it is used extensively for this purpose; reports indicate that efforts are being made to extend its use in countries where supplies of fuels customarily used are deficient.

IMPORTS

In 1939, before the war became world-wide, peat moss imported for consumption in the United States totaled 78,611 short tons valued at $1,204,883. In 1942 the quantity imported was 49,236 tons, but the reported value of $1,219,473 was slightly greater than the value of 1939 imports. Imports were received from 15 countries in 1939, and in that year, as in many earlier years, Germany was the chief source of supply. Netherlands and Sweden also exported large quantities of peat moss to the United States. In 1942 all imports came from Canada and the United Kingdom, the former supplying 49,100 tons and the latter only 136 tons. In 1939 imports from Canada were only 6,922 tons and those from the United Kingdom 785 tons. It is evident from these figures that Canada, now supplying much of the peat moss imported, has replaced Germany, Sweden, Netherlands, and other European countries as the source of imported peat.

Peat moss imported for consumption in the United States, 1937–42

Year	Short tons	Value	Year	Short tons	Value
1937	86,871	$1,219,127	1940	21,689	$454,632
1938	69,509	1,092,942	1941	30,342	704,264
1939	78,611	1,204,883	1942	49,236	1,219,473

With the drastic reduction of imports subsequent to 1939, peat producers in the United States were presented with an excellent opportunity to expand their markets and increase production; however, the closing of some plants because of labor shortages and curtailment of activities at others for the same reason prevented operators from taking full advantage of the situation in 1942.

The pre-war values of the imported product are considerably lower than those of 1942. The average value per ton was $15.33 in 1939, compared with $24.77 a ton for 1942. This increase is attributable almost entirely to the high value of the Canadian product.

WORLD PRODUCTION

Reports from some foreign countries indicate that peat is being used extensively as fuel; however, complete production data cannot be obtained until after the war. The following table shows available statistics on world output of peat, 1938–42.

World production of peat, 1938–42, by countries [1]

GENERAL REVIEW

Outstanding effects of the war on the supply and demand for all oils in 1942 were the sharp decline in civilian gasoline demand owing to the necessity of conserving both tires and motor vehicles; the readjustments in refinery operations and yields resulting from the drop in gasoline demand and the rise in fuel-oil requirements; a major recession in imports, accompanied by a substantial gain in exports; the drastic curtailment of oil consumption in the Atlantic Coast States resulting from the diversion of tankers to war uses and the substitution of new overland transport routes; and the large increase in the total demand for oil in the Pacific Coast district.

The total demand for all oils reached a peak of 1,595 million barrels in 1941 and decreased about 32 million barrels (2 percent) in 1942. The principal changes compared with 1941 were a drop of 72 million barrels in the total demand for motor fuel, a gain of almost 20 million barrels in the total demand for residual fuel oil, and an increase of 17 million barrels in the demand for distillate fuel oil. The decline in total demand would have been greater except for liquidation of almost 37 million barrels of stocks of refined oils in areas where normal transportation facilities were sharply curtailed. In the East Coast district such stocks were reduced almost to bare working levels. In view of the large increases in the direct war demands for oil products, a substantial increase in total demand might have been expected in 1942 rather than a decrease. To visualize the effect of various restrictions on civilian consumption properly it would be necessary to set up an estimated normal demand for 1942 rather than to make direct comparisons between actual 1941 and 1942 data.

[1] Data for 1942 are preliminary; detailed statistics with final revisions will be released later.

Digitized by Google

The progressive readjustment in refinery operations in 1942 resulted from a 5-percent decline in the amount of crude refined as well as from the substantial gain in fuel-oil demand and the sharp reduction in gasoline demand. This situation was complicated further by a 62-million barrel drop in imports, consisting primarily of heavy crude and fuel oils. As the result of these various factors, the average yield of gasoline was reduced 4.5 percent, whereas the yield of residual fuel oil was increased 2.6 percent and that of distillate fuel 1.3 percent.

The production of crude petroleum totaled 1,385 million barrels in 1942, and the demand for domestic crude petroleum amounted to 1,395 million barrels. Compared with 1941, there was a decline of 17 million barrels in crude production and a decrease of 26 million barrels in crude demand. The recession in total demand for all oils and the large withdrawals from refined stocks tended to reduce the demand for domestic crude petroleum, but the effect was largely offset by the sharp drop in total imports.

Total demand for all oils in the United States, 1933–42

[Millions of barrels]

Year	Domestic demand	Exports	Total demand	Year	Domestic demand	Exports	Total demand
1933	868.5	106.7	975.2	1938	1,137.1	193.7	1,330.8
1934	920.2	114.5	1,034.7	1939	1,231.1	188.9	1,420.0
1935	983.7	129.0	1,112.7	1940	1,326.6	130.5	1,457.1
1936	1,092.7	132.0	1,224.7	1941	1,485.8	108.8	1,594.6
1937	1,169.7	172.8	1,342.5	1942 [1]	1,442.0	121.1	1,563.1

[1] Subject to revision.

The combined demand for motor fuel, residual fuel oil, and distillate fuel oil represents about 80 percent of the total demand for all oils. A brief review of the demand and supply trends for these three products will reflect the most significant changes in the oil situation in 1942 compared with 1941.

The total demand for motor fuel declined from 695 million barrels in 1941 to 622 million in 1942—a 10-percent decrease. The average yield of gasoline from crude petroleum fell from 44.2 percent in 1941 to 39.7 percent in 1942. The refinery output was supplemented by a reduction of over 15 million barrels in finished gasoline stocks compared with an increase of over 8 million barrels in 1941. Exports of motor fuel rose from 27 million barrels in 1941 to 36 million in 1942, and domestic demand decreased from 667 million barrels in 1941 to 586 million in 1942. As the rapidly expanding military requirements for gasoline are included in domestic demand, the decline in civilian consumption was materially greater than the total decline in domestic demand. According to the best estimates available, the decline in the civilian automotive use of motor fuel in 1942 was about 105 million barrels or approximately 18 percent. In evaluating the actual effect of the curtailment in civilian consumption, this decline might reasonably be compared with an expectation of at least a 5-percent normal increase in 1942 based upon the increase in the number of motor vehicles in use on January 1, 1942, compared with January 1, 1941. As the total indicated decline in gasoline demand in the Eastern States (Petroleum Administration for War District 1) was about 46 million barrels in 1942, it would appear that about half of the total national decline in civilian automotive use occurred in that area.

Digitized by Google

The total demand for residual fuel oil rose to 417 million barrels in 1942—a gain of almost 20 million barrels or 5 percent compared with 1941. This increase was all in domestic demand, as exports showed a small decline. Three major changes of about equal importance featured domestic demand. Railroad consumption increased by about 20 million barrels, the rise in naval requirements was probably of similar magnitude, and a decline of about the same amount is indicated as the result of conversions to coal and rationing. On the supply side, imports were 20 million barrels less; withdrawals from storage rose from 5 million barrels in 1941 to 21 million in 1942; transfers from crude to residual were 6 million barrels greater; and refinery production increased from 342 million barrels in 1941 to 359 million in 1942, with an increase in yield from 24.3 percent to 26.9 percent.

The total demand for distillate fuel oil increased from 190 million barrels in 1941 to 207 million in 1942—a 9-percent gain. Exports rose from 17 million barrels to 23 million and domestic demand from 173 million barrels to 184 million. About 70 percent of the total domestic demand is used for heating purposes. In view of the larger number of oil-heating installations in use in 1942, a substantial

Digitized by Google

increase in demand was anticipated, but this expected gain was reduced by the rationing program effective in the last quarter of 1942. The principal changes in supply in 1942 were a decrease of about 2 million barrels in imports, a reduction of over 4 million barrels in stocks compared with a stock increase of 7 million in 1941, and a gain of about 8 million barrels in refinery production with an increase in yield from 13.4 percent in 1941 to 14.7 percent in 1942.

From a regional viewpoint, the outstanding changes in oil demand in 1942 were the rapid rise in demand in the Pacific Coast district and the sharp curtailment in normal consumption in the Atlantic Coast States. California was the main source of oil supply for war operations in the Pacific and an important supplier of fuel for expanding war industries and increasing railroad traffic. The Atlantic Coast area consumed about 38 percent of the total demand for all oils in 1941 and felt the full effect of the major disturbances in transportation in 1942.

The increase in the total demand for all oils in the Pacific Coast area has been one of the major results of the changes due to the war. The demand for all oils approximated 246 million barrels in both 1939 and 1940. It rose to 256 million barrels in 1941 and to 279 million in 1942. Exports and noncontiguous shipments have dropped steadily from 61 million barrels in 1939 to 23 million in 1942. Shipments by boat and rail to States outside the Pacific Coast market area have likewise slumped from about 11 million barrels in 1939 to 3 million in 1942. This sharp reduction in outside shipments has been much more than offset by the rapid increase in railroad, war industry, and military and naval requirements in the five States constituting the dometic market area. This domestic demand has increased from about 174 million barrels in 1939 to 213 million in 1941 and 253 million in 1942. The major factor in the 40-million-barrel gain in domestic demand in 1942 was the 28-million-barrel increase in the demand for heavy fuel oils. The production of crude petroleum in 1942 was 24 million barrels above the 1939–40 level and was supplemented by a withdrawal from stocks of all oils of about 12 million barrels.

In contrast with the sharp rise in oil demand in the Pacific Coast district, the war has brought a severe curtailment of consumption in the Atlantic Coast States. The indicated demand for all oils in this area (Petroleum Administration for War District 1) fell from 607 million barrels in 1941 to 509 million in 1942—a decline of 98 million barrels (16 percent). In normal times, the major part of the supply was delivered by boat from the Gulf coast and from foreign sources. The diversion of tankers to war uses shifted the burden of transportation to new overland routes that required organization of a huge tank-car movement, construction of new pipe lines, and increased use of inland waterways. The total indicated demand for motor fuel rose from 214 million barrels in 1940 to 236 million in 1941 and was reduced to about 190 million in 1942—a decline of 19 percent for the year. Compared with 1941, gasoline consumption during the first quarter of 1942 showed a slight gain but was reduced by 23 percent in the second quarter, by 28 percent in the third quarter, and by 23 percent in the fourth quarter. A sharp reduction in deliveries to distributors was followed by inauguration of a gasoline-rationing system in May that reduced civilian consumption more drastically

Digitized by Google

than in other districts, where rubber conservation was the main objective.

The supply of residual fuel oil presented a problem second only to that of motor fuel. The long-distance movements of residual oil depended on tanker transport, owing to lower cost and the inherent difficulty of moving this heavy product by either tank car or pipe line. A program was begun early in the year to urge industrial consumers to convert from fuel oil to coal, and these conversions had reached an annual rate of over 30 million barrels in District 1 by the end of the year. The alarming depletion of the total stocks of all oils led to establishment, on October 1, of a system for rationing heating oils in both the Atlantic Coast area and in the Middle West. Although the cumulative effect of these measures made it possible to meet the most essential requirements during the winter months, an adequate civilian supply for this district remains one of the acute problems in 1943.

A brief review of the major factors in the trend of oil supply and demand, by quarters, beginning with the last quarter of 1941 and extending through the first quarter of 1943, will give a better perspective of the results of increasing war requirements and of progressive restrictions on less essential civilian uses.

The demand for all oils reached an all-time peak of 422 million barrels in the last quarter of 1941, with daily average crude production at a peak of 4,107,000 barrels and crude runs at a peak of 4,058,000 barrels daily for the quarter.

The total demand for all oils dropped to 408 million barrels in the first quarter of 1942, but this amount was still almost 11 percent greater than for the same period in 1941. War requirements were increasing, and the need for curtailing civilian demands was just becoming apparent. The decline in imports was relatively small, and demand was sustained further by a reduction of over 27 million barrels in the stocks of refined oils, compared to a liquidation of only 7 million barrels for the same period of 1941. Compared with the first quarter of 1941, average runs to stills gained 146,000 barrels daily and crude production 366,000 barrels daily, although about one-half of this increase was reflected in a rise in crude stocks. The total demand for motor fuel increased by almost 5 percent, for residual fuel oil by over 12 percent, and for distillate fuel oil by almost 12 percent.

In the second quarter of 1942 the effects of the disturbance in normal transportation and the necessity of conserving rubber became more apparent. The demand for all oils was almost 3 percent less than in the same period of 1941. Imports declined 16 million barrels, refined stocks were reduced almost 21 million barrels, and crude stocks dropped over 11 million barrels. Compared with the second quarter of 1941, average runs to stills decreased 323,000 barrels daily and crude production 203,000 barrels daily. The reduction of almost 11 percent in the total demand for motor fuel was the major factor, accompanied by smaller relative gains of 6 percent in the total demand for residual fuel oil and about 9 percent for distillate fuel oil. With rapidly dwindling stocks and reduced tanker movements, the supply situation in the East coast became a serious problem, and steps were taken to restrict civilian consumption of motor fuel and to urge industrial plants using fuel oil to convert to coal.

[2] Preliminary figures for Jan. 1, 1942.

Digitized by Google

In the third quarter of 1942, the demand for all oils was 9 percent less than in the same period of 1941. Imports were almost 23 million barrels less. Efforts to rebuild depleted stocks of refined oils resulted in a gain of about 10 million barrels, but crude stocks were reduced further by 12 million barrels. Although crude runs and crude production were substantially above the low levels of the second quarter, the daily average was still 305,000 and 112,000 barrels, respectively, below the third quarter of 1941. The total demand for motor fuel showed a relative decline of 17 percent from the previous year, while the gain in residual demand was less than 5 percent and for distillate fuel oil only 6 percent. A gasoline-rationing system was inaugurated in May in the Eastern States, restrictions were placed on the distribution of distillate fuel oil, and further conversions of industrial plants from oil to coal became effective.

The total demand for all oils was only about 5 percent less in the last quarter of 1942 than in the same period of 1941. Imports were 22 million barrels less than in 1941. Crude production and runs to stills continued to rise, but the daily averages were, respectively, 228,000 and 340,000 barrels daily below the all-time peaks of the last quarter of 1941. The total demand for gasoline showed a relative decline of over 15 percent, whereas the demand for residual fuel oil increased only 2 percent and for distillate fuel oil about 8 percent above the previous year. Gasoline rationing was established on a Nation-wide basis in December, but its effect on total demand was obscured by heavy advance stocking by consumers. Inauguration of the rationing of heating oils in the main consuming areas on October 1 reduced potential demand materially, but the effect was modified by the substantial gain in the number of installations compared with the previous year. The small gain in residual demand indicated that the large increases in naval and railroad consumption were largely offset by the cumulative effect of conversions to coal, of increased prices, or of actual inability to procure adequate supplies in some districts.

The total demand for all oils in the first quarter of 1943 was about 9 percent less than in the same period of 1942 but was almost 1 percent greater than the comparatively low level of the first quarter of 1941. For the succeeding quarters of 1943, total demand may exceed the 1942 levels, as war requirements and exports progressively increase and as civilian consumption reaches essential minimum levels.

RESERVES

Reserves of crude oil on January 1, 1943, were estimated by the American Petroleum Institute Committee on Petroleum Reserves at 20,082,793,000 barrels. These reserves include only crude oil and distillate in known and proved fields and recoverable by present production methods. Additions to reserves during 1942 totaled 1,878,976,000 barrels; but only 260,051,000 barrels represented new pools discovered during the year, and 1,618,925,000 barrels represented upward revisions of reserve estimates for fields discovered before 1942. Although estimated reserves are more than 14 times the amount of petroleum produced in the peak year 1941, warnings of a shortage are increasing. It was pointed out that if the demands for this nation and its allies increased materially, new discoveries would be necessary to supply these requirements and yet keep within an efficient rate of production.

[1] From reports of Committee on Petroleum Reserves, American Petroleum Institute, of the amount of crude oil that may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonably accurate calculations. The change in reserves during any year represents total new discoveries, extensions, and revisions minus production.

LEGISLATION AND ADMINISTRATION

Among the legislation affecting the petroleum industry was the O'Mahoney Act, signed December 24. This act, although passed too late to influence operations in 1942, is designed to promote exploration on public lands. It provides a flat 12½-percent royalty for 10 years on all oil and gas produced from new wells in newly discovered fields on public lands in place of the "Step-scale rates" provided for in the act of 1935. Another law suspends antitrust action on acts done to further the war program, and yet another gives the Army and Navy pewor to force reductions in patent royalties.

Administrative orders by agencies appointed by the President put the petroleum industry under wartime regulation. The principal agencies involved were the Office of Defense Transportation, the Office of Price Administration, and the Office of Petroleum Coordinator (changed toward the end of the year to Petroleum Administration for War).

The Petroleum Administration for War, in addition to being made a claimant agency (an agency that has the right to claim a priority on scarce material), was given the power to issue instructions and orders relating to all phases of the industry and the means for enforcing such instructions and orders.

Office of Petroleum Coordinator Conservation Order M–68 and War Production Board Preference Rating Order P–98 were two im-

Digitized by Google

portant regulatory measures in effect during 1942. The former limited drilling, with exceptions, to one well to each 40 acres and provided for easy acquisition of drilling and operating material and supplies by operators who conform to the regulation. This order eliminated the drilling of an estimated 13,000 wells, with the result that the use of steel for drilling in defined fields was reduced to 60 percent of that in 1941. Even greater curtailment is promised in future, with a much wider spacing pattern.

Preference Rating Order P–98 enabled oil operators to get priority ratings on scarce material under the Priorities Rating Plan (PRP). The Controlled Materials Plan (CMP), a new plan for distributing scarce materials, came into use January 1, 1943, 6 months being allowed for the transition period from the old PRP to the CMP. Under the CMP certain agencies, designated as claimant agencies, submit requirements for scarce material to the Controlled Materials Division of the War Production Board. The Controlled Materials Division then analyzes the requirement claims and makes allotments to the claimant agencies through its Requirements Committee, which is made up of representatives from each of the claimant agencies, in addition to one from the Department of State. Claimant agencies then distribute the allotments to the qualified consumers. The Petroleum Administration for War was made a claimant agency under this plan.

Office of Petroleum Coordinator Directive 59 called for the joint use of facilities among persons engaged in the petroleum industry and the joint use of their products in Districts 1, 2, and 3. It was designed to eliminate crosshauling and to assure, as far as possible, an equitable proportion of stocks and of sales among the supplies in each area. These acts, illegal under the Sherman antitrust law, were approved by legislation passed in 1942 suspending antitrust action on acts done to further the war program.

Other administrative acts affecting the petroleum industry included prohibition of the use of tank cars in the Midwest; prohibition of use of tin, terneplate, and blackplate for motor-oil cans; prohibition of gasoline shipments from the East coast; prohibition of use of benzene in motor fuel; prohibitions on the use of asphalt and road oil; placing of butadiene under allocation control; setting Nation-wide automobile speed limit, first at 40 miles per hour then at 35; making United States refining processes available to Russia; directing the shipments of specific quantities of products from Districts 2 and 3 to District 1; modifying refinery yields; prohibition of manufacture of domestic oil burners; prohibition of movement of gasoline to East coast by tank car in favor of fuel oil; and prohibition of use of credit cards for gasoline.

PRORATION

Early in 1942 the Office of Petroleum Coordinator assumed the function of prescribing the rates of crude-oil production for the States in place of the estimates of market demand that had been issued by the Bureau of Mines theretofore. The Bureau of Mines continued to issue the monthly forecast of motor fuel and crude-oil requirements and to supply the Office of Petroleum Coordinator with estimates of the market demand for crude oil for the individual States.

Digitized by Google

Production recommendations by the Office of Petroleum Coordinator included consideration of reserves and of efficient production rates as well as market demand. Beginning in April, recommendations for production comprised all petroleum liquids, including condensate and natural-gas derivatives as well as crude oil.

Proration in the past generally has been based upon dividing the production determined necessary, so that each well received its share based upon the proration formula in effect. Thus a purchaser might be required to fill part of his needs with an oil that he did not desire because the proration theory required that the demand be divided proportionately among all the oils. War conditions, however, changed this aspect of proration in 1942, and wells producing crudes suitable for aviation gasoline, high-grade lubricants, and other military requirements were given preference.

The Interstate Oil Compact Commission voted at the December meeting to extend the life of the compact to September 1, 1947.

The table usually appearing in this section showing market-demand estimates, State allowables, and production has been suspended because Petroleum Administration for War certified production rates, which have supplanted the Bureau of Mines estimates of market demand, include natural gasoline and distillates and are not comparable with crude-oil production.

CRUDE PETROLEUM

SUPPLY AND DEMAND

The total demand for crude petroleum was approximately 1,410 million barrels in 1942, compared with 1,472 million in 1941—a reduction of about 62 million barrels or 4 percent. This decline was due to a drop in the total demand for all oils and an abnormal liquidation of stocks of refined oils. A 75-million-barrel decrease in crude runs to stills was partly offset by a 13-million-barrel rise in crude used for fuel and losses and a slight gain in crude exports. Compared with 1941, domestic crude production declined by about 17 million barrels, crude imports were reduced by 38 million barrels, and total withdrawals from crude stocks were only 12 million barrels or 7 million less than in 1941.

PRODUCTION

General.—Crude-oil output of 1,385,479,000 barrels was 16,749,000 barrels less than the 1,402,228,000 produced in 1941. Greatest declines were in Illinois—25,937,000 barrels; Texas—22,201,000; and Oklahoma—14,012,000. Production increased 18,063,000 barrels in California and 14,394,000 in Kansas.

The relative importance of the three outstanding producing States—Texas, California, and Oklahoma—declined further, so that in 1942 they supplied only 63.0 percent of the country total compared with 63.5 percent in 1941 and 64.5 percent in 1940 (see fig. 3).

East Texas remained the greatest producing field, despite a decline in 1942. The Wilmington (Calif.) field rose to second place and the Tinsley (Miss.) field to third.

Arkansas.—Output in Arkansas in 1942 of 26,628,000 barrels was but slightly more than the 26,327,000 barrels produced in 1941. Declines in most of the fields were offset by production of 1,218,000 barrels from the new Midway field in Lafayette County, discovered in January. Twenty-nine producing wells were completed in this field, with an average initial daily production of 101 barrels per well. Eleven completions, with an average initial daily production of 155 barrels, raised the production in the Stephens field 150 percent, but the 1942 production totaled only 614,000 barrels.

There were 103 completions in 1942, with an initial daily average production of 121 barrels, compared with 95 completions in 1941, with an average initial daily production of 190 barrels.

California.—The urgent need for heavy crude oils to produce naval and industrial fuels prompted a comprehensive survey and planned efforts to increase the production of such oils. Success was indicated by about 45 percent more production of heavy crude at the end of the year than at the beginning. Total crude-oil production in California amounted to 248,326,000 barrels in 1942, or 18,063,000 more than in

Digitized by Google

1941; 13,459,000 barrels of this increase was in heavy crude, which raised the total output of that type to 40,716,000 barrels.

Biggest gain was in the San Joaquin Valley district, where production totaled 105,075,000 barrels compared with 93,811,000 in 1941. The heavy-oil fields of Coalinga, Mount Poso, and Midway-Sunset were principally responsible for this gain. Coalinga's 5,099,000-barrel increase was accompanied by the completion of 43 oil wells with an average initial daily production of 645 barrels. Twenty-six wells were completed in the Mount Poso field, with an average daily initial production of 101 barrels, and the output increased from 4,117,000 barrels in 1941 to 7,566,000 in 1942. Activity in Midway-Sunset interrupted a downward trend in production from that field, with an increase from 17,461,000 barrels to 20,470,000. Sixty-two wells were drilled, with an average initial production of 74 barrels.

Danger to marine transportation and transfer of tankers to other services have restricted production in the Coastal district, where more oil can be produced when transportation facilities are available to move it. The production of 33,948,000 barrels from this district was 1,724,000 barrels more than in 1941. Contributing to this was 1,217,000 barrels from the long-dormant Gato Ridge field, which was brought back to production early in the year. Although 29 wells with an average initial of 586 barrels were completed in the Santa Maria Valley field, the production of 7,550,000 barrels was only 642,000 barrels more than in 1941. Output in the Ventura Avenue field was increased 752,000 barrels to 13,644,000, aided by 16 completions with an average initial of 1,151 barrels.

The Los Angeles Basin produced 109,303,000 barrels—a gain of 5,075,000 barrels. Largest rise was in the Wilmington field, where a 2,985,000-barrel increase raised the total production to 33,657,000 barrels—the second largest in the country. Thirty-eight wells with an average initial of 245 barrels were completed in Wilmington in 1942. Huntington Beach and Inglewood also made large gains in output.

Five hundred fifty-seven oil wells were completed in California in 1942 with an average intial of 358 barrels, compared with 920 wells in 1941 with an average initial of 712 barrels. Dry holes totaled 247 compared with 179 in 1941.

The Wilmington field maintained its place by a generous margin as the largest field in the State, with Midway-Sunset and Coalinga next in order. Further decline in the Kettleman Hills light-oil field dropped it to sixth place.

Colorado.—Production of 2,220,000 barrels represented a small increase over the 2,150,000-barrel output of 1941. The only fields to show material increases were Wilson Creek, which rose from 453,000 barrels in 1941 to 533,000 in 1942, and Rangely, which rose from 220,000 barrels in 1941 to 288,000 in 1942.

Ten wells were completed in Colorado during 1942 compared with 16 in 1941. Four of the completions were in Rangely and 4 in Wilson Creek.

Production of crude petroleum in Colorado, 1938–42, by fields

[Thousands of barrels]

Year	Florence [1]	Fort Collins [2]	Iles	Moffat	Price	Rangely	Tow Creek	Wilson Creek	Other fields	Total
1938	64	109	819	126	185	32	56	----------	21	1,412

Illinois.—Further decline in Illinois production from 132,393,000 barrels in 1941 to 106,456,000 in 1942 forecasts a greater burden on Texas, Kansas, and other sources for supplying the Great Lakes and Eastern United States areas with petroleum in future. The Salem field, whose 70,734,000 barrel output in 1940 was exceeded by the East Texas field only, dropped to second place in the State in 1942, with a

Digitized by Google

production of 14,705,000 barrels. This was a slump of more than 50 percent from the 29,539,000 barrels produced in 1941. The Louden field, though declining, produced 17,961,000 barrels in 1942 and wrested first place from Salem.

New oil wells completed totaled 1,107—59 percent less than the 2,730 completed in 1941. The average initial dropped to 168 barrels compared with 277 in 1941 and 620 in 1940.

Greatest activity was in the Rural Hill Field in Hamilton County, discovered in 1941. Seventy-six wells were completed in this field, with an average initial of 189 barrels. Production from the Dale-Hoodville field in the same county decreased from 6,195,000 barrels in 1941 to 5,294,000 in 1942 following completion of 74 wells with an average initial of 236 barrels. Notwithstanding 53 completions with an average initial of 119 barrels in the New Harmony field in White County, production in that field declined from 9,939,000 barrels in 1941 to 7,224,000 in 1942.

[1] Oil and Gas Journal.

[2] Included in Dale.

None of the new fields discovered compared with the larger ones of 1941. The Covington pool in Wayne County, discovered in August, was the most important. Twenty-three wells were completed in this pool, with an average initial of 479 barrels and a total production of 1,159,000 barrels up to the end of the year. Oil was found in the Benoist sand of the Boulder pool in Clinton County during the first part of the year; but it was not until October, when a well was completed to the Devonian with an initial of approximately 700 barrels,

Digitized by Google

that its importance was established. The 23 wells drilled in this field in 1942 had an average initial of 128 barrels. The St. Jacob pool, discovered in Madison County in May, is particularly important because it established a substantial production in the Trenton limestone, which has heretofore been considered unimportant. The 23 wells completed in this pool had an average initial of 213 barrels.

Indiana.—Despite the discovery of 12 new pools during 1942, production in Indiana declined to 6,743,000 barrels from 7,411,000 in 1941. More than half of the production came from the Griffin field.

Oil-well completions totaled 126 compared with 262 in 1941. Greatest activity was in Gibson and Posey Counties. Discovery of production in the Devonian lime in the Dodds Bridge area in Sullivan County was the most important find of the year.

Production of crude petroleum in Indiana, 1938–42, by months

[Thousands of barrels]

Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total

Kansas.—A strong demand for Kansas crude oil, brought about by the decline in Illinois and Oklahoma production, resulted in intense activity in that State in 1942. The 1941 record output was exceeded by 17 percent. Reduction in drilling (forced by Regulation M–68) was relatively less than in any of the other major producing States except California, and the relative increase in wildcat wells drilled was greater than in any other major producing State.

The production of 97,636,000 barrels was 14,394,000 higher than the 83,242,000 barrels in 1941. Oil-well completions, totaling 813, had an average initial of 693 barrels compared with 1,420 wells of 1,032 barrels average initial in 1941; 351 wildcat wells were drilled compared with 214 in 1941.

Greatest activity was in the Peace Creek field in Reno County, where 102 wells were completed with an average initial of 827 barrels. Although output for the year totaled 1,650,000 barrels, there are indications that this field will be much more prominent in future. The Kraft-Prusa field in Barton County completed 74 wells with an average initial of 773 barrels. Fifty-two completions in the neighboring Trapp-Sellers field, with an average initial of 738 barrels, gave it the highest production of any in the State—9,726,000 barrels.

The Petroleum Administration for War certified production rate for petroleum liquids in Kansas was raised from 253,400 barrels daily in April to 300,700 for December. Scarcity of equipment makes it difficult for operators who installed small-capacity pumping units adapted to past allowables to obtain larger equipment. They are unable to produce the greater quota, but neighboring operators who have larger pumping units in the same fields are permitted to obtain a greater share of the oil because of the higher allowable.

Kentucky.—Production in Kentucky continued its downward trend until near the end of 1942, the total for the year being 4,472,000 barrels compared with 4,762,000 in 1941. During the year 48 oil wells were completed compared with 233 in 1941. Production was increased materially during November and December by the development of the Smith Mills field in Henderson County, discovered in August. Production is from the McClosky lime and Cypress sand.

Louisiana.—Production of 115,726,000 barrels in Louisiana was slightly less than the 115,908,000-barrel output of 1941.

The output of the Gulf Coast area dropped 4,387,000 barrels from 90,917,000 barrels in 1941 to 86,530,000 in 1942. The decline was general, with little change in the relative standing of the large fields. Ville Platte maintained first place, producing 6,446,000 barrels (a gain of 327,000) as a result of 19 completions, with an average initial of 171 barrels. A smaller decline in the Golden Meadows field than in the Jennings put the former in second place.

The greatest gain—from 1,085,000 barrels in 1941 to 2,246,000 in 1942—and the greatest activity were in the Paradis field in St. Charles Parish. The 27 completions had an average initial of 417 barrels. The Chalkley field in Cameron Parish gained 860,000 barrels to 1,514,000. Sixteen completions in the Bayou Sale field in St. Mary Parish, with an average initial of 196 barrels, raised the year's production from the field to 943,000 barrels.

Production in northern Louisiana declined generally, but gains in the Haynesville, Olla, Little Creek, and Nebo fields raised the total output to 29,196,000 barrels from 24,991,000 in 1941.

Greatest activity during 1942 was in the old Haynesville field, where production in the Pettit lime was discovered late in 1941; 120 wells were completed, with an average initial of 412 barrels, and the output rose from 956,000 barrels in 1941 to 4,621,000 in 1942.

The Olla field proper produced approximately 4,650,000 barrels, placing it slightly ahead of Haynesville, although it should be noted that "Olla" production includes approximately 1,300,000 barrels from the Little Creek field and approximately 200,000 from the Summerville field. The increase in Olla proper was approximately 400,000 barrels and that in Little Creek approximately 900,000. Twelve oil wells were completed in Little Creek, with an average initial of 153 barrels, and 3 in Olla, with an average initial of 106 barrels.

An increase from 974,000 barrels in 1941 to 3,424,000 in 1942 raised the Nebo field to fourth largest in the State, following Rodessa. Nebo was the second most active field, with 52 wells completed, but the average initial was only 44 barrels.

In 1942, 564 oil wells were completed in Louisiana with an average of 227 barrels. Of these, 286 were in the Gulf Coast area, with an average initial of 237 barrels, and 278 were in northern Louisiana, with an average initial of 216 barrels. This compares with 1,081 completions in 1941 (467 in northern Louisiana and 616 in Gulf Louisiana), with an average initial of 189 barrels.

Michigan.—Production from new fields brought the crude-oil output in 1942 to 21,754,000 barrels, which was exceeded only in the record year 1939.

The Reed City pool in Osceola County, discovered late in 1940, was the largest field in 1942, supplying 9,102,000 barrels compared with 2,754,000 in 1941. The Evart pool, discovered in May 1942 in the same county, contributed 169,000 barrels additional. This county had the greatest activity in the State, as 66 wells were drilled in the

Digitized by Google

Reed City pool and 15 in the Evart, with an average initial of 1,942 barrels for the 81 wells.

The Headquarters pool in Roscommon County was second largest, with an output of 2,321,000 barrels compared with 315,000 in 1941, its discovery year. Sixteen wells were completed in this pool and, with 11 others in the same county, had an average initial of 1,303 barrels. Completion of 43 wells in Bay County, with an average initial of 121 barrels, increased the production to only 485,000 barrels.

In all, 293 oil wells were completed in Michigan during 1942, with an average initial of 827 barrels. The Evart pool, mentioned above, was the most prolific discovery of 1942, in terms of initial production; but the Aetna, Norwich, and Riverside fields, discovered in Missaukee County, are significant because of development of production in hitherto barren territory.

Production of crude petroleum in Michigan, 1938–42, by fields [1]

[Thousands of barrels]

Year	Adams	Bloomingdale	Buckeye	Headquarters	Porter	Redding	Reed City	Sherman	Walker	Winterfield	Other fields	Total

[1] Data from Department of Conservation, Michigan.

Mississippi.—Although production in 1942 was 28,833,000 barrels compared with 15,327,000 in 1941, the trend during the latter part of the year was downward, dropping from 96,000 barrels daily in April to 60,000 in December. Virtually all of the production was from the Tinsley field, only a small amount coming from the Pickens, Sharpsburg, and Cary fields. All of the locations in the Tinsley field have now been drilled, and there is little probability of output in Mississippi increasing unless further discoveries are made. This is reflected in the drop in completions from 219 in 1941 to 20 in 1942.

Production of crude petroleum in Mississippi, 1939–42, by months

[1] Subject to revision.

Montana.—An increase of 548,000 barrels raised crude-oil production in Montana to 8,074,000 barrels in 1942. Principally responsible was the Cut Bank field, where the production was 5,509,000 barrels—489,000 more than in 1941. Seventy-five wells were completed in this field, with an average initial of 150 barrels. Completion of 46 wells in the Kevin-Sunburst field, with an average initial of 47 barrels,

Digitized by Google

was reflected in an increase in production from 1,753,000 barrels in 1941 to 1,992,000 in 1942. All the other fields, of small production, declined.

There were 123 wells completed in the State, with an average initial of 109 barrels.

Nebraska.—Production in 1942 totaled 1,237,000 barrels compared with 1,898,000 in 1941. The output declined rapidly from the peak of 221,000 barrels in October 1941 to 78,000 in December 1942. The Falls City field supplied two-thirds of the total and the Barada field a little less than one-third.

Ten wells were completed in the State in 1942, seven of them in the Barada field and two in the Falls City field.

Production of crude petroleum in Nebraska, 1939–42, by months

New Mexico.—A sharp decline brought production down to 31,544,000 barrels in 1942 compared with 39,569,000 in the peak year 1941. The decline was general, and Maljamar was the only major field producing more in 1942 than in 1941. The Monument field maintained first place, with the neighboring Eunice field second.

The greatest drilling activity was in the Square Lake pool in Eddy County, discovered early in 1942. Ninety-two wells were completed in this field, with an average initial of 179 barrels. The total output for the year was 290,000 barrels. Completions in the Maljamar field totaled 35, with an average initial of 219 barrels, and 32 wells were completed in the Jackson-Grayburg field, with an average initial of 164 barrels. Although only 9 wells each were completed in the Arrowhead and Loco Hills fields, their average initial was 393 and 372 barrels, respectively.

New York.—Greater drilling activity further increased the output in New York to 5,421,000 barrels compared with 5,185,000 in 1941. New completions, according to the Oil Weekly, totaled 711 compared with 674 in 1941. New York was one of the four States where 1942 completions were greater than those in 1941.

Ohio.—The production of 3,543,000 barrels in 1942 was slightly higher than the 3,510,000 produced in 1941. Production of Pennsylvania-Grade oil increased from 1,459,000 barrels in 1941 to 1,637,000 in 1942. Greatest activity was in Perry County, where Pennsylvania-Grade oil is produced and 80 oil wells were completed; the Clayton pool was extended both northward and westward. Washington County had 28 completions and neighboring Monroe County 15. Medina County, in the central part of the State, had 24 completions. Completions for the State totaled 235.

Production of crude petroleum in Ohio, 1938–42, by months

Oklahoma.—Production in Oklahoma declined to 140,690,000 barrels from 154,702,000 in 1941. The largest reduction was in the Oklahoma City field, which dropped to 26,484,000 barrels from

Digitized by Google

32,184,000 in 1941, although the field maintained first place. Seminole, the second largest field, dropped to 20,408,000 barrels from 23,687,000 in 1941. Production in the Hewitt field was 3,304,000 barrels and in Osage 4,716,000, representing losses of 32 percent and 23 percent.

In 1942, 544 wells were completed in the State, with an average initial of 374 barrels, compared with 1,099 wells with an average initial of 226 barrels in 1941. Greatest activity was in the Hotulke field, Pottawatomie County, where new production was discovered in 1941 in the Viola and Wilcox formations. Thirty-four wells were completed in this field, with an average initial of 256 barrels. The St. Louis field in the same county, which was extended north and east in 1941, had 24 completions, with an average initial of 237 barrels. The Apache field, discovered in Caddo County in 1941, had 19 completions, with an average initial of 2,381 barrels.

Outstanding was the discovery of the Pauls Valley field in Garvin County in April. Thirteen wells completed in this field had the unusually high average initial of 5,253 barrels, from the Wilcox and Pennsylvanian formations. The Watchorn field, discovered in Pawnee County in May, had 11 completions, with an average initial of 551 barrels from the Wilcox, and the Ardmore pool discovered in Carter County in October had 2 completions in the Springer Sand, which had an average initial of 666, barrels.

Pennsylvania.—Although the crude-oil output of 17,779,000 barrels was more than a million barrels higher than in 1941, the trend was downward after midyear, despite a price increase designed to encourage development. Although production was the largest since 1937, crude-oil stocks of Pennsylvania origin declined from 2,142,000 barrels at the end of 1941 to 1,610,000 at the end of 1942.

Pennsylvania and New York suffered less from drilling restrictions than any other State; the oil-well completions in Pennsylvania, as reported by the Oil Weekly, increased from 1,722 to 1,802, although those in the Bradford field (partly in New York) declined from 1,540 to 1,493.

Production of crude petroleum in Pennsylvania, 1938–42, by months

[1] Subject to revision.

Texas.—Texas production receded 4 percent from its 1941 record of 505,572,000 barrels to 483,371,000 in 1942. Only the Panhandle area had a substantial gain, and losses in some areas were relatively large. Oil wells completed totaled 3,049 compared with 7,262 in 1941.

A slight increase brought production in the Gulf Coast area to 135,020,000 barrels. The Conroe field maintained its lead and gained 1,884,000 barrels to produce 13,514,000 in 1942. Hastings, however, had the largest gain—2,789,000 barrels—which brought its production to 10,412,000. Saxet, largest field in 1938, produced only 2,728,000 barrels in 1942.

There were 724 wells completed in the Gulf Coast area, with an average initial of 165 barrels, compared with 1,353 in 1941, with an average of 196 barrels. Greatest activity was in the Withers-Magnet field, where 62 wells were completed, with an average initial of 136 barrels, and where production increased from 2,829,000 barrels in 1941 to 4,165,000 in 1942. The Seeligson field, discovered in Jim Wells County in April 1941, had 61 completions, with an average initial of 125 barrels. There were 55 completions each in the North La Ward and Stratton fields, 38 in the Agua Dulce, and 32 in the Odem field.

The Mercy field, discovered in January 1942 in San Jacinto County, was a most important find, as it is believed to include one of the largest areas of Wilcox sand of any field in the State. There were seven completions, with an average initial of 409 barrels. Another discovery in the Wilcox sand was Camp Eleven in Tyler County, where two completions had an average initial of 594 barrels.

Production in West Texas totaled 81,775,000 barrels, compared with 92,907,000 in 1941. The Wasson field, despite a decline of 3,719,000 barrels—from 13,120,000 to 9,401,000—still ranked first. The Slaughter-Dean pool, however (with a gain of 2,732,000 barrels to 7,531,000), promises to overtake it. A 859,000-barrel gain gave

Digitized by Google

Yates 6,749,000, displacing Goldsmith, which dropped from 8,232,000 barrels to 6,569,000.

In West Texas, 1,079 oil wells were completed, with an average initial of 825 barrels, compared with 2,123 wells averaging 841 barrels in 1941. This material decline resulted from the lack of pipe-line facilities more than from the restraints on drilling from Regulation M–68 (previously described). Greatest activity was in the Slaughter field, where 421 completions had an average initial of 1,051 barrels from the San Andres lime. Wasson was the next most active field, with 93 completions and an average initial of 555 barrels; despite this, output declined 28 percent. The Keystone-Colby pool had 45 completions and the Abell pool 40, with 233 barrels and 983 barrels average initial, respectively.

Andrews County led in discoveries. Principal among the eight new fields and extensions in this county was Fullerton, discovered in February. Eight wells were completed in the field, with an average initial of 810 barrels from the Clear Fork lime. The Embar pool, discovered in this county in May, had five completions in the Ellenburger formation, with an average initial of 864 barrels. Two other wells that failed to find oil in the Ellenburger were plugged back to the Clear Fork lime and yielded an average initial of 262 barrels.

One of the most significant discoveries relating to reserves was production from the Ellenburger formation in the Monahans pool, Ward County, in May. The one well drilled had an initial of 2,852 barrels. One other well drilled to the Clear Fork lime in this pool had an initial of 759 barrels.

Production from eastern Texas totaled 153,707,000 barrels, compared with 159,960,000 in 1941. The East Texas field proper declined 9,615,000 barrels to 122,871,000. Only five small wells were completed in this field during the year, compared with 428 in 1941. Talco had the next highest production—9,522,000 barrels—and Hawkins was third at 5,451,000.

There were 240 completions in eastern Texas, with an average initial of 228 barrels, compared with 798 wells averaging 160 barrels plus 16 border wells completed in 1941. Greatest activity was in the Hawkins field, Wood County, discovered in 1940; 133 wells were completed, with an average initial of 202 barrels. Chapel Hill, in Smith County, also discovered in 1940, had 29 completions, with an average initial of 289 barrels.

Wood County had two new discoveries in 1942 in the Paluxy sand; these were the Coke and Quitman pools. The Coke pool, found in June, had 25 completions for an average initial of 416 barrels; the Quitman pool was found on December 1, and the discovery well produced an initial of 726 barrels daily. The Kildare pool, discovered in Cass County in March, had eight completions with an average initial of 388 barrels from the Gloyd lime; and the Weiland pool, discovered in Hunt County in June, had 6 completions with an average initial of 183 barrels from the Woodbine sand.

Production in North Texas totaled 49,851,000 barrels compared with 48,529,000 in 1941. Principally responsible for the increase was development of the Ellenburger formation of the K. M. A. pool, output of which rose from 613,000 barrels in 1941 to 2,168,000 in 1942, more than offsetting the drop in yield from the shallower formations in this field. Total production for the field was 11,219,000 barrels. Of the

Digitized by Google

94 wells drilled in this field, 57 were to the Ellenburger and had an average initial of 849 barrels. The 37 other wells averaged 334 barrels. Before 1941 Ellenburger production was inconsequential in North Texas, but development in the K. M. A. field and other fields where it has since been found has added substantially to North Texas reserves.

The Hull-Silk field, with only five new completions, held second place with 3,819,000 barrels—virtually the same output as in 1941.

North Texas had 527 completions during 1942, with an average initial of 304 barrels, compared with 1,727 in 1941, with an average initial of 192 barrels. Next to K. M. A., greatest activity was in the Wimberly field in Jones County, where 29 wells were completed, with an average initial of 331 barrels.

The Forestburg pool, discovered in May in Montague County, was one of the most important finds of the year. Seven completions in this pool had an average initial of 1,071 barrels. The Sanders pool, discovered in this same county in April, had three completions, with an average initial of 1,320 barrels. The Padgitt pool, discovered in Young County in June, had three completions, with an average initial of 1,448 barrels. Other important discoveries were the Hoefle pool in Jack County, the Cooker pool in Coleman County, and the Reddin pool in Taylor County.

Central Texas had a discovery of especial significance—the South Caesar field in Bee County, found in February. Twelve oil wells have been completed with an average initial of 338 barrels, from the Carrizo sand.

Panhandle Texas reaped the benefit in 1942 from the 1941 drilling activity, which raised the monthly production 50 percent between the beginning and end of 1941. This area, with its increase in production from 27,831,000 barrels in 1941 to 30,881,000 in 1942, was the only one of major importance in Texas to show a substantial gain. Completions totaled 258 compared with 648 in 1941.

Wyoming.—Production in Wyoming increased from 29,878,000 barrels in 1941 to 31,392,000 in 1942. Lance Creek, the principal field, decreased from 8,838,000 barrels to 7,823,000 despite the completion of 12 wells with an average initial of 171 barrels.

Although Salt Creek again declined, it maintained second place with 4,989,000 barrels output, followed closely by Oregon Basin, with a yield of 4,711,000 barrels compared with 3,197,000 in 1941. Good transportation, the need for heavy oil, and prospects for higher prices for that type of crude combined to focus attention on this field. Accordingly, 27 wells were completed, with an average initial of 451 barrels.

Ninety-three oil wells were completed in the State, with an average initial of 317 barrels, compared with 123 completions averaging 395 barrels in 1941. One of the most important finds of the year was production in November in the deep Tensleep formation of the Elk Basin field. A discovery of promising possibilities was the Horsecreek field in Laramie County in November. The one well completed in this field had an initial production of 580 barrels from the Lakota sand. New production was found in the Pilot Butte field in the Tensleep sand in March and in the Embar lime in September. The Tensleep discovery well had an initial of 750 barrels and the Embar discovery 500 barrels, which later turned to water.

WELLS

The number of wells drilled in the United States in 1942, including oil and gas wells and dry holes, dropped 39 percent to 17,934 compared with 29,070 in 1941.

Oil-well completions declined 46 percent—from 19,195 in 1941 to 10,302 in 1942. Regulation M–68 (previously described) was the principal reason for such severe curtailment, although exhaustion of drilling sites and lack of transportation to market for production already acquired were contributing causes.

The greatest relative decline was in Mississippi, where exhaustion of drilling locations caused completions to drop 91 percent from 219 in 1941 to 20 in 1942. The 3,049 wells completed in Texas were 58 percent less than the 7,262 completed in 1941, and the ratio of completions to total for the United States dropped from 38 percent in 1941 to 30 in 1942. The 1,107 completions in Illinois were 59 percent less than the 2,730 in 1941, and only 11 percent of the total wells drilled in the United States were drilled in this State compared with 14 percent in 1941. The relative number of oil wells completed in the Eastern States rose from 15 percent in 1941 to 26 percent in 1942, but the actual number declined from 2,895 to 2,662, or 8 percent.

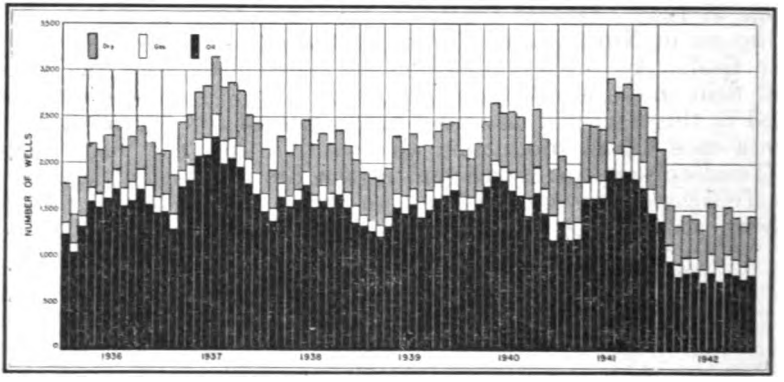

FIGURE 4.—Wells drilled in the United States, 1936–42, by months.

The 5,532 dry holes drilled in 1942 were 20 percent less than the 6,885 drilled in 1941. The smaller decline, compared with oil-well completions, reflects the lack of restrictions under Regulation M–68 against obtaining material for exploratory wells. However, difficulty in getting equipment, even with priorities, and in getting drilling crews because of lack of manpower, as well as narrowing margins of profit as drilling costs advanced against a stable crude-oil price contributed toward curtailment of exploratory operations. The Office of Price Administration proposed that the Government subsidize the cost of drilling exploratory wells to stimulate the search for new reserves yet avoid raising the price of oil. Of the total wells drilled, 3,166 were exploratory; 466 discovered oil and 57 gas, and 2,643 were dry.

The average depth per well drilled, according to the Oil Weekly, was 3,038 feet compared with 2,963 feet in 1941. Deeper drilling to

Digitized by Google

reach new production discovered in lower formations was partly offset by such factors as relatively fewer wells drilled in Illinois and Texas, where formations are deep, compared with eastern fields in which a relatively greater number of wells were drilled; and emphasis in California on heavy-oil production, the deposits of which are nearer the surface than those of light oil.

STOCKS

Total crude-oil stocks declined about 12 million barrels in 1942 compared with about 19 million barrels in 1941. An increase of over 16 million barrels in the first quarter was due to the disruption of transportation, resulting in abnormal liquidation of 27 million barrels of refined stocks that reduced the expected demand for domestic crude petroleum. While the draft on refined stocks continued during the second quarter, a sharp drop in crude production and in crude imports resulted in a decrease of about 11 million barrels in crude stocks. In spite of a substantial recovery in production, crude stocks dropped 12 million barrels more in the third quarter, mainly because of low imports of crude and efforts to rebuild stocks of refined products. In the fourth quarter, the seasonal rise in the demand for all oils resulted in an increased production of crude as well as a further reduction of about 5 million barrels in crude stocks. Total stocks of crude petroleum amounted to 245,219,000 barrels on December 31, 1942, compared with 257,063,000 barrels on December 31, 1942. Stocks of foreign crude declined over 2 million barrels, and stocks of domestic origin were reduced by almost 10 million barrels.

[1] Subject to revision.
[2] For comparison with succeeding year.
[3] Includes equivalents for wax, coke, and asphalt in barrels.

The data on stocks of crude oil, by States of origin for 1942, show that the largest decreases were 12.7 million for Oklahoma, 9.0 million for Illinois, and 2.1 million for California crude of all grades. Smaller declines occurred in the stocks of all other important producing States except Texas, where stocks increased about 21.7 million barrels. These figures reflect chiefly the result of the decline in tanker movements from the Gulf to the East Coast district and the necessity of liquidating crude stocks located closer to consuming centers during the period of establishing new transport routes.

CONSUMPTION AND DISTRIBUTION

Runs to stills.—Crude runs to stills declined sharply to a total of 1,334 million barrels in 1942—a drop of 75 million barrels (5.3 percent) below the peak level of 1941. The decrease in foreign crude runs was 36 million barrels and in domestic crude runs 39 million barrels. The reduction in refinery output was due to a 2-percent decline in the total demand for all oils and to a liquidation of about 47 million barrels of stocks of refined oils.

The change in refinery operations by districts varied greatly in 1942 compared with a substantial increase in all districts in 1941. Crude runs declined by about 56 million barrels in both the East Coast and Texas Gulf Coast districts, owing to the sharp curtailment in tanker movements and to the necessity of meeting demand by heavy withdrawals from stocks of refined oils in the East Coast area. The new overland movements inaugurated to supply this deficit stimulated refinery operations in the Middle West. Crude runs gained 4 million barrels in the Appalachian district and 13 million barrels in the Indiana-Illinois-Kentucky district. Crude runs in the California district rose to 230 million barrels—a gain of 17 million—owing to the increased demand by war industries, railroads, and the Navy.

Distribution.—The total demand for domestic crude petroleum fell from 1,421 million barrels in 1941 to 1,395 million barrels in 1942, or less than 2 percent. The effects of the reduction in crude runs and the liquidation of refined stocks were materially offset by the decrease of 62 million barrels in the imports of all oils, necessitating replacement of this loss in supply, at least in part, from domestic sources. All of these factors contributed to a disturbance in normal movements of crude petroleum and in the relative demand for domestic crude petroleum by States of origin.

Receipts of domestic and foreign crude petroleum at United States refineries totaled 1,410 million barrels in 1941 and 1,328 million in 1942. In 1942 receipts of foreign crude petroleum at refineries were only about 12 million barrels, or less than 1 percent of the total compared with 3.6 percent in 1941; interstate receipts of domestic crude were 521 million barrels or 39.2 percent compared with 38.6 percent in 1941; and intrastate receipts were almost 795 million barrels or 59.8 percent compared with 57.8 percent in 1941.

Refinery receipts of crude in 1942, by methods of transportation, indicated that 80.0 percent of the total was delivered by pipe lines compared with 73.9 percent in 1941; that 9.9 percent was delivered by boat compared with 22.7 in 1941; and that 10.1 percent was delivered by tank car and truck compared with 3.4 percent in 1941. These figures indicate the sharp decline in boat movements and the relative gain in overland shipments.

The most important changes in the market demand for crude petroleum by States of origin (computed from production and changes in crude stocks by origin) in 1942 compared with 1941 were increases of about 18 million barrels for California, 16 million for Mississippi, 14 million for Kansas, and 7 million for Michigan. The largest declines in crude demand were about 46 million barrels for Texas, 19 million for Illinois, 13 million for Oklahoma, and 7 million for New Mexico. These changes indicate shifts in production trends, in accessibility to market under disturbed transportation conditions, and in the availability of accumulated stocks.

The total demand for Texas crude declined from 507 million barrels in 1941 to 462 million in 1942—a loss of about 9 percent. In 1942 about 310 million barrels of Texas crude were delivered to refineries within the State—a decrease of 34 million compared with 1941. Shipments to refineries in other States amounted to about 138 million barrels or 8 million less than in 1941. Deliveries to East Coast refineries declined from 108 million barrels to 76 million but increased to the Illinois, Indiana, Kentucky, etc., district from 23 million barrels to 42 million in 1942. The sharp drop in the demand for crude petroleum resulted in an increase of almost 22 million barrels in stocks of Texas origin.

The demand for California crude increased from 232 million barrels in 1941 to over 250 million in 1942—a gain of almost 8 percent. Crude production was about 16 million barrels higher and was supplemented by a decrease of about 2 million barrels in stocks. Most of the crude was refined in the State, except for small exports to western Canada. The increase in crude demand was supplemented further by a decline of about 9 million barrels in stocks of refined oils.

The market demand for Oklahoma crude declined from 166 million barrels in 1941 to 153 million in 1942. This decrease was due primarily to a further decline in production, as the liquidation of about 13 million barrels in stocks of origin was only 1 million barrels greater than in 1941. Deliveries to refineries within the State declined by about 4 million barrels to 52 million barrels. About 15 million barrels were delivered to refineries in Kansas and Missouri, 62 million barrels to Illinois-Indiana, Ohio, and Michigan refineries, about 15 million barrels to East Coast refineries, about 6 million to the Appalachian district, and about 7 million barrels to refineries in Texas.

The market demand for Illinois crude continued to decline as production decreased. Crude production was only about 106 million barrels in 1942—26 million less than in 1941. A decrease of 9 million barrels in stocks of Illinois origin raised crude demand to over 115 million barrels in 1942, but this amount was still 19 million barrels less than in 1941. Deliveries to refineries in Illinois amounted to 34 million barrels in 1942—a decrease of 7 million compared with 1941. Shipments to refineries in other States totaled 63 million barrels, of which 35 million went to other States in the Indiana, Illinois, Kentucky, etc., district, 19 million to the Appalachian district, and 9 million to the East Coast district. The decline in the available supply of Illinois crude contributed to the transportation problems in 1942.

The demand for Louisiana crude in 1942—116 million barrels—was virtually the same as in 1941. Deliveries to refineries within the State showed a substantial increase in 1942 to a total of about 44 million barrels, and shipments to refineries in the East Coast district increased slightly, approximating 22 million barrels. Deliveries to the Texas Gulf Coast district decreased in proportion to gains in other districts.

The demand for Kansas crude rose to 98 million barrels in 1942. The gain of 14 million barrels, compared with 1941, approximated the increase in crude production. Deliveries to refineries in Kansas amounted to 44 million barrels; and interstate shipments increased substantially, with a total of 34 million barrels to Indiana and Illinois and about 7 million to refineries in the East Coast district.

Digitized by Google

The demand for New Mexico crude totaled 33 million barrels in 1942—a decline of 7 million compared with 1941. About 2 million barrels were delivered to refineries in the State. Shipments to the East Coast district declined about 5 million barrels and to Texas refineries about 3 million, whereas deliveries to the Illinois-Indiana district gained 1 million barrels.

The demand for Wyoming crude increased about 3 million barrels to total 33 million in 1942. An increase in production and stock liquidation contributed to this gain in about equal proportions. Deliveries of almost 14 million barrels to refineries in the State were slightly less than in 1941. Deliveries to adjacent States in the Mountain district rose from 9 million barrels in 1941 to 10 million in 1942, and deliveries to Kansas and Indiana refineries increased over 2 million barrels.

The demand for Mississippi crude increased from almost 14 million barrels in 1941 to almost 30 million in 1942. Deliveries to Louisiana and Texas refineries declined from about 9 million barrels in 1941 to less than 5 million in 1942. Shipments to the East Coast district rose from about 1 million barrels in 1941 to 10 million in 1942; deliveries to Kentucky, Ohio, and Illinois refineries amounted to over 14 million barrels—a gain of 9 million compared with 1941.

The demand for Arkansas crude remained virtually stationary at about 27 million barrels in 1942. Intrastate deliveries represented about half of the total demand. Shipments to Louisiana declined, but the northward movements increased substantially.

The demand for Michigan crude rose from less than 16 million barrels in 1941 to over 22 million in 1942, owing primarily to a gain in production. Over 17 million barrels were delivered to refineries in the State; most of the balance went to Ohio refineries.

The demand for Pennsylvania crude amounted to over 18 million barrels in 1942 compared with less than 17 million in 1941. About two-thirds of the increase was due to a gain in production and the remainder to stock liquidation.

PRICES AND VALUE

No year since 1934 has been so uneventful as 1942 in price changes for crude. The Office of Price Administration permitted only one change throughout the year in fields of major importance—an advance of 25 cents per barrel for Pennsylvania-Grade crude oil on March 26.

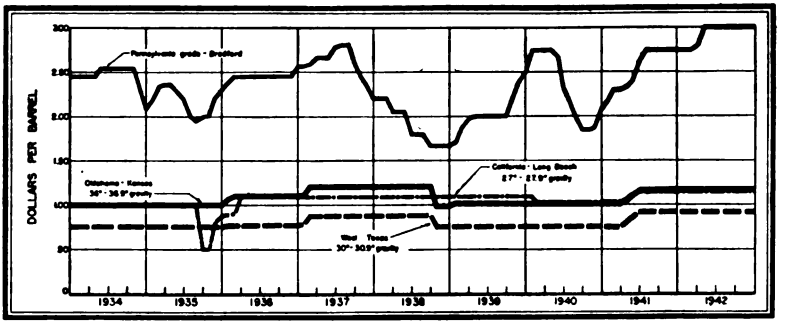

FIGURE 5.—Posted prices of selected grades of crude petroleum in the United States, 1934–42, by months.

REFINED PRODUCTS

GENERAL REVIEW

The first full year of war brought revolutionary changes in the petroleum industry. The importance of petroleum in the last war is insignificant compared with the responsibilities the industry is carrying in the present conflict. The tremendous tasks in meeting these responsibilities have brought about major alterations in the refining, transportation, and marketing of petroleum products.

War economy necessitated conversion by the refiners from a basis of producing motor fuel for automobiles as their principal output to the production of larger proportions of fuel oils, high-octane gasoline for aviation fuel, butadiene for rubber, and aromatics for toluene, cumene, and styrene; and to the construction of alcohol plants for the manufacture of rubber and explosives. The changes required entirely new sections for some refineries, whereas others had to be used with minimum changes because of scarcity of material.

Transfer of tankers to war functions threw the burden of supplying the heavily populated East Coast States on other modes of transportation—principally tank cars and pipe lines. With these facilities already insufficient to bring the full requirements to the East, the situation was aggravated by the need of shipping part of the military requirements for the North African campaign from East Coast ports.

[1] Subject to revision.
[2] Negative quantity; represents net excess of unfinished oils rerun over unfinished oils produced.
[3] Negative quantity (overage).

The inadequate receipts of oil on the eastern seaboard necessitated steps to conserve the supply, including pooling of stocks and facilities of the various companies and the rationing of gasoline and heating oil. Domestic demand for motor fuel in the East Coast district during the four summer months of 1942 was cut 29 percent below that of 1941. Individual sales were of smaller gallonage, partly to permit retailers to ration their limited stocks among their customers and partly because the customers filled their tanks more frequently to avoid letting supplies get low.

Fuel-oil rationing started with a prohibition against filling home owners' tanks in the East Coast and Great Lakes areas during the summer, the usual time for replenishing the supply. This, together with an unusually cold winter and the greater number of trips necessitated because of the smaller quantity they were permitted to deliver at one time, made it difficult for retailers to deliver even the reduced quantities permitted by the rations.

The effect of these disruptions in the industry on other economic phases of national life was shown in the loss of investment by the closing of thousands of service stations and the release of their owners and workers for other branches of the war industry; the closing of roadside restaurants, tourist camps, and similar businesses; and the drop of $146,000,000 in State and Federal gasoline taxes, with a certainty of even less income from gasoline taxes in 1943.

Digitized by Google

Domestic demand for motor fuel dropped 12 percent—from 667 million barrels in 1941 to 586 million in 1942. An increase in exports from 27 to 36 million barrels, however, made the loss in total demand only 72 million barrels. Domestic demand for distillate fuel oil rose from 173 million to 184 million barrels and for residual fuel oil from 383 million to 403 million barrels. Exports of distillate fuel—23 million barrels—were 6 million higher than the 1941 exports, but exports of residual fuel oil declined about ½ million barrels.

Summary of percentage yields of refined products in the United States, 1934–42

[Computed on total crude runs to stills]

Product	1934	1935	1936	1937	1938	1939	1940	1941	1942 [1]

[1] Subject to revision.
[2] Negative percentage: represents excess percentage rerun over percentage produced.
[3] Less than 0.1 percent.

Greater need for heavy oils and diminishing requirements for motor fuel forced modification in refinery operations that resulted in a drop in gasoline yield from 44.2 percent of the crude oil run to stills in 1941 to 39.7 percent in 1942. Distillate fuel-oil yields rose from 13.4 percent in 1941 to 14.7 percent in 1942 and residual fuel-oil yields from 24.3 percent to 26.9, but kerosine yields declined from 5.2 percent to 5.1.

The East Coast and Texas Gulf Coast districts were almost entirely responsible for the decline in crude-oil runs to stills. Transportation difficulties, restricting the supply of crude oil for East coast refiners

Digitized by Google

and depriving the Texas Gulf Coast district of its principal market for gasoline, resulted in a drop of 26 percent—from 217 million barrels in 1941 to 161 million in 1942—in the East Coast district and a drop of 16 percent—from 363 million barrels in 1941 to 307 million in 1942—in the Texas Gulf Coast district. California, with an 8-percent gain, had the greatest increase in crude runs; and the Appalachian district, with a gain of 7.3 percent, and the Indiana, Illinois, Kentucky, etc., district, with a 5.2-percent increase, followed in relative gains.

The freezing of refined-oil prices, effective November 7, 1941, was followed in 1942 by more definite regulations from the Office of Price Administration. Schedule 88, signed February 2, covered most prices except those at the service stations and provided that prices in effect

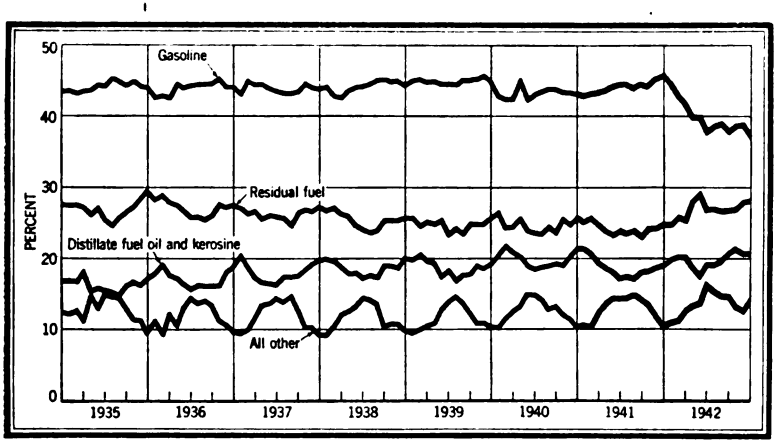

FIGURE 6.—Yields of principal petroleum products from crude oil run to stills in the United States, 1935–42, by months.

October 1, 1941, should be ceiling prices for petroleum and petroleum products. Maximum Price Regulation 137, issued April 28 and effective May 18, froze all retail prices for motor fuel and Diesel fuel at the highest March 1942 level. The General Maximum Price Regulation, also issued April 28, applied to all commodities and services not covered specifically by individual price schedules. It became effective for producer, manufacturer, and wholesaler prices on May 11, for retail prices on May 18, and for services on July 1 and likewise established the highest price charged by the individual seller during March 1942 as his maximum. As most oil prices were covered by Schedule 88 and Regulation 137, this General Regulation applied principally to services.

A number of amendments have changed the ceiling prices for refined oils; the chief of them are increases to offset higher transportation costs, the rescinding of 2½ cents of the increase in gasoline prices in eastern cities when the Defense Supply Corporation assumed a like amount of the cost, and the amendment of December 26 permitting retailers to maintain a 3-cent margin between the cost and selling price of gasoline.

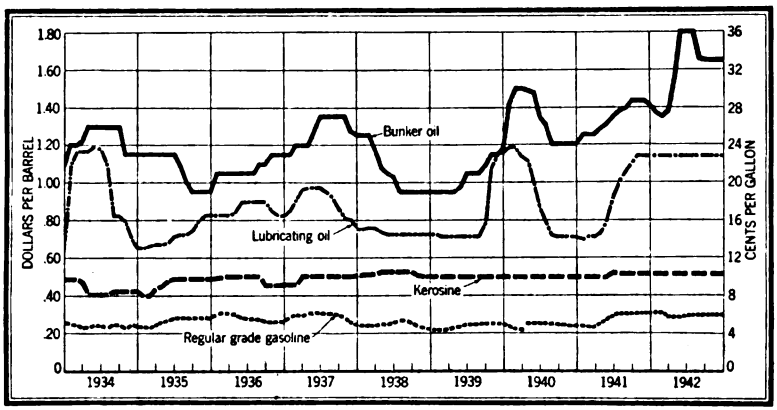

FIGURE 7.—Prices of Bunker "C" fuel oil at New York, bright stock at Oklahoma refineries, tank-wagon price of kerosine at Chicago, and regular-grade gasoline at refineries in Oklahoma, 1934–42, by months.

REFINING

Refinery capacity.—The total number of refineries dropped from 523 on January 1, 1942, to 472 on January 1, 1943, but crude-oil capacity rose from 4,999,999 barrels daily to 5,092,411.

Cracking capacity retired in 1942 was virtually the same as that added, resulting in almost no change in completed capacity as of the beginning of 1943. Capacity in the process of construction on January 1, 1943, however, amounted to 154,984 barrels daily, which would bring the total capacity on that date to 1,347,867 barrels, compared with 1,222,684 on January 1, 1942. New processes are developing so rapidly in cracking that equipment becomes obsolete in a very short time; and it is possible that retirement of capacity will keep pace with additions, particularly in view of the declining need for gasoline and the difficulty in supplying demands for heavy oils.

The small gain in crude-oil capacity during 1942 belies the turmoil of construction throughout the country. All new refinery construction had the object of supplying war requirements, including aviation gasoline, butadiene, toluene, and alcohol, in addition to less-emphasized products. Much of the new equipment was to be used in making special commodities from certain unfinished fractions, which explains why the crude-oil capacity did not increase commensurately with activity.

Government interest in the production of aviation gasoline increased rapidly during 1942. When Lease-Lend requirements began depleting stocks during the latter months of 1941 and the declaration of war shocked authorities into the realization that plant capacity must be expanded rapidly, 100-octane gasoline production became

Summary of refinery capacity in the United States, January 1, 1939–43

Year	Number of refineries				Capacity (barrels per day)			
	Operating	Shut down	Building	Total	Operating	Shut down	Building	Total
1939	435	103	7	545	3,933,785	574,770	142,250	4,650,805
1940	461	86	10	557	4,196,694	431,952	92,567	4,721,213
1941	420	136	6	562	4,180,588	538,381	141,225	4,860,194
1942	430	92	1	523	4,496,843	459,756	43,400	4,999,999
1943	386	85	1	472	4,404,213	493,098	195,100	5,092,411

one of the Nation's most important projects. Late in 1941 it was decided that 40,000 barrels per day of 100-octane gasoline were needed. After war was declared this was trebled, only to be raised in about 2 months to 180,000 barrels and soon thereafter to 250,000 barrels a day—a goal which was on the way toward accomplishment at the end of 1942, but even then was threatened with lack of material. More than 50 plants were either completed or under construction for the production of 100-octane gasoline at the end of 1942. A number of other refineries were producing the lower grades of aviation gasoline, mainly a 91-octane.

The synthetic rubber program was still handicapped by delay at the end of 1942 because of adverse weather and difficulties in obtaining priorities for critical materials. The delay in getting construction under way had prompted the appointment by the President of the Baruch Committee to investigate the rubber situation and make recommendations for expediting the program. The report of this committee, in addition to the appointment of a rubber director, led to rationing of gasoline to save tires and modified earlier plans for synthetic rubber manufacture.

Two plans were promulgated for producing rubber from petroleum—a long-range plan for permanent plants and a refinery-conversion or "quick" butadiene plan. Contracts were made in pursuance of the long-range plan for plants with a capacity of 310,000 tons annually to produce butadiene by catalytic dehydrogenation of butane and butylene in addition to 220,000 tons' capacity of plants to produce butadiene from alcohol. The first of the dehydrogenation plants, started in 1941, was completed early in 1943, and three others were completed during the immediately succeeding months. Under the second plan, 14 refineries with an annual capacity of approximately 160,000 tons had been authorized for conversion at the end of 1942, but the contracts for several of them were canceled later.

Technical developments.—During recent years technical research has taken a role of greater importance than ever before, and the discoveries and developments therefrom have changed refining from simple fractionation of petroleum to a complicated chemical industry. Wartime secrecy prevents disclosing most of the new discoveries, which include solvents, plastics, alcohol, ammonia, synthetic silks, and many others.

Developments announced during the year included moving catalysts, which foreshadow abandonment of fixed catalysts. A moving catalyst momentarily contacts the oil vapor, which travels in a parallel stream; then, the reaction completed, the two separate, and the

Digitized by Google

catalyst is regenerated away from the cracking chamber. The moving catalyst, in addition to the time saved in regeneration and the yield of a better product, presents a saving in steel that is important at this time.

Other progress during the year promises higher-octane gasoline and includes new developments in cracking and isomerization. The first oil company to receive the Army-Navy "E" was cited for its performance in producing 100-octane gasoline, toluene, and marine lubricants, particularly turbine oils.

TRANSPORTATION

This Nation and its allies were fortunate that it had been customary to supply Atlantic coast oil needs from the Gulf coast by boat. Because of this, the second-largest and one of the best-equipped tanker fleets in the world was available for military use upon declaration of war.

Shifting a large part of these boats to military and Lend-Lease service, however, brought radical changes in the methods of transporting oil and in the social and economic life of the American people. The transfer, plus interference by submarines, resulted in tanker shipments of petroleum and its products from the Gulf area to the East coast being reduced from 430,769,000 barrels in 1941 to 123,831,000 in 1942. The daily average during the last 5 months of 1942 had dwindled to 143,000 barrels compared with 1,180,000 for 1941. The largest part of the oil requirements for the eastern United States had to be supplied by overland transportation, and a sizable proportion of the military needs was also shipped from East coast ports.

Every means available was used to move oil to the Atlantic seaboard, although economic considerations kept some facilities unavailable during the first part of 1942. Ceiling prices were too low to pay the cost of transportation in many cases, particularly on boat shipments of fuel oil from the Great Lakes area, and this kept some facilities idle that should have been in service. This defect was largely remedied later in the year; the Defense Supplies Corporation assumed the excessive carrying costs when it was deemed expedient to involve greater transportation expenses than customary without a compensatory increase in prices.

Greatest dependence for moving oil to the East coast was placed upon the railroads. Tank-car shipments in December 1941, already increased because of difficulties in marine transportation, averaged 62,000 barrels daily. From this average they mounted to a peak of 856,710 barrels daily for 1 week in September. Tank cars were pooled, loading and unloading time was cut to the minimum, and shipments from individual refiners were grouped at assembly points from which full trains of oil cars were dispatched as express freight. Further readjustment was required and in August transportation of gasoline by tank car was prohibited in 20 of the Midwestern and Southwestern States.

Other developments and projects to aid in the distribution of oil included improvement in barge transportation, expansion and confining of tank trucks to short hauls, use of steel drums for transporting kerosine in box cars, and revamping and expanding the pipe-line system.

Although by far the greatest dependence was put upon the railroads in 1942 for moving oil to the East coast, pipe lines did their part, and projects completed or under construction will relieve the railroads of a large part of the burden of supplying the Atlantic seaboard with petroleum and its products.

The war concept of the pipe line is that it is merely a part of a whole, to be used as best serves the national war strategy. Changes resulting from this war concept involve much new construction and relocation, reversing, and other rearrangement of old pipe lines. Projects initiated included the laying of more than 2,300 miles of new line, taking up and relocating 1,700 miles of second-hand pipe, and converting 2,800 miles of other lines.

The most important of these changes was the construction of the "Big Inch"—the 24-inch line from east Texas to southern Illinois. It is the longest and largest pipe line ever laid for transporting oil. Oil began to move through this line in February 1943. Construction of an extension to carry the products from Illinois to the East coast was initiated toward the end of 1942.

A 60,000-barrel feeder line was started from Houston and Port Arthur to Baton Rouge to contribute toward the supplies for the Plantation line, completed early in 1942. In addition, the terminus of the Plantation line was being extended from Greensboro, N. C., to Richmond, Va.

Other projects started or planned during 1942 include a 35,000-barrel-daily products line across Florida, a 15,000-barrel-daily line across Ohio, and the Sinclair line from Steubenville, Ohio, across Pennsylvania. Pipe-line completions during 1942 include reversal and conversion of the Keystone line across Pennsylvania, reversal of the Sun-Susquehanna line from Cleveland to the eastern seaboard, enlargement of the Shell line from Wood River, Ill., to Lima, Ohio, enlargement of the Texas-Empire line between Tulsa and Chicago, and reversal and conversion of a Texas Co. pipe line between Port Arthur and Dallas, Tex. The 24- to 26-inch Stanpac natural-gas pipe line, extending from Kettleman Hills to San Francisco, has been converted to crude-oil service, with a capacity of 100,000 barrels daily.

MARKETING

Curtailment of oil along the Atlantic seaboard introduced a new experience to people living in that area—the rationing of gasoline and fuel oil and the regulation of the use of automobiles for certain purposes. Although lack of fuel oil caused considerable inconvenience and some suffering, the rationing of gasoline probably necessitated more severe readjustments in living habits.

The responsibility of rationing was placed under control of the Office of Price Administration. Gasoline rationing was initiated in the 17 Atlantic Coast States and the District of Columbia on May 17. Rationing was extended to the rest of the country on December 1, but the purpose was to save tires rather than to conserve a deficient supply of gasoline.

Heating-oil rationing was initiated in 30 Eastern and Midwestern States on October 1, after prohibition of sales during the summer. Rationing of heating oil was necessitated by an actual shortage in fuel oil as well as by difficulties in transportation. The problem of

Digitized by Google

fuel oil, however, differed from that of gasoline in that abundant supplies of coal exist close to the centers of population, and fuel-oil users were urged to convert their facilities to coal-burning equipment wherever possible.

MOTOR FUEL

Domestic demand for motor fuel in 1942 was influenced by factors tending in opposite directions, but the elevating factors exerted less influence than the depressing ones.

Accelerated military demand came to represent a material share of the consumption in 1942, and the increasing need for transportation of war workers took an additionally larger proportion of civilian consumption as the year progressed.

The depressing factors were shortage of tires and rationing of gasoline. Realization of the limited future supply of tires was reflected in some curtailment of traffic early in 1942, although the momentum of the up-sweep of gasoline consumption largely concealed this retarding influence, and it was not until the second quarter that it began to be obvious.

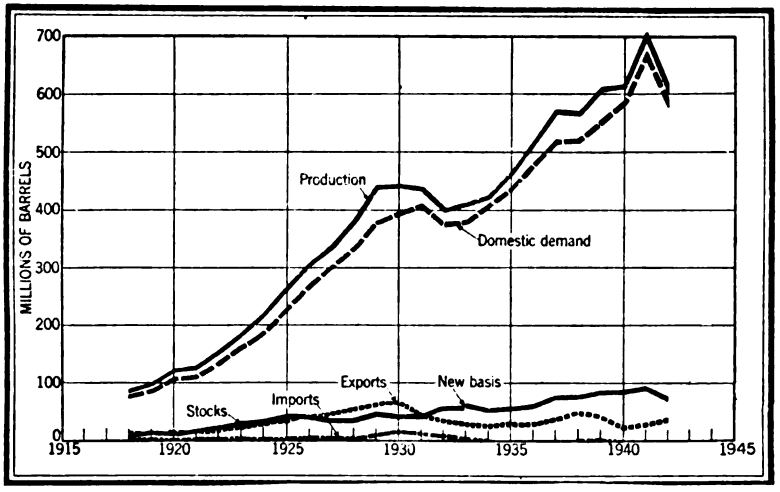

FIGURE 8.—Trends of production, domestic demand, exports, imports, and stocks of motor fuel in the United States, 1918–42.

Transportation difficulties prompted the Office of Petroleum Coordinator to issue its Curtailment Order L–70, which limited deliveries of gasoline to the East Coast area and the Pacific Northwest, effective April 16, to two-thirds of normal. Considerable confusion resulted from the difficulty of service stations in accommodating customers, and limited sales and "No Gas" signs became common. This condition was improved only slightly when the Office of Price Administration, under authority from the War Production Board, instituted gasoline rationing on May 15 in the 17 East Coast States and the District of Columbia. Ration allowances for larger quantities than the retailers were permitted to obtain under Order L–70 complicated the retailers' difficulty in supplying the demand. Coupon rationing, instituted July 15, whereby the retailer exchanged

the coupons he collected from the motorist for new supplies, largely eliminated the excessive demand, although there were frequent instances of dry tanks at service stations.

Nation-wide rationing of gasoline was instituted on December 1. Whereas rationing in the East Coast area resulted from insufficient supplies because of transportation difficulties, that consideration did not enter into the Nation-wide rationing, which was adopted to conserve tires.

Under the coupon system the basic ration was 4 gallons a week for each car, supplemental quantities being issued where it was necessary

Digitized by Google

for a motorist to use his car to drive to war work or in performing war work, or where commercial users were assisting the production of war needs. During the winter coupon values were reduced to 3 gallons in the East Coast area, and early in 1943 pleasure driving was prohibited. When it was again permitted in March 1943, the basic ration was cut to 1½ gallons a week.

Domestic demand.—Domestic demand for motor fuel was 586,088,000 barrels, or 12 percent less than the 667,505,000 barrels in 1941. Automotive demand dropped 18 percent—from 583,957,000 barrels in 1941 to 478,691,000 in 1942.

Distribution of domestic motor-fuel demand in the United States, 1938–42

[1] Subject to revision.

Traffic statistics indicate that at many points truck traffic was greater on the highways in 1942 than in 1941 notwithstanding difficulty in obtaining tires and gasoline. This was particularly true in California, where there were large increases on some highways; there was even a gain in long-distance travel (indicated by trucks entering the State), which was 1 percent higher than in 1941, compared with a drop of 44 percent for passenger cars. The instances were rare where passenger-car traffic on the highways was greater than in 1941, some points in California being the principal exceptions.

Excepting California, city traffic was lower for both trucks and passenger cars, although traffic for the latter was affected considerably more than the former.

Passenger cars in use July 1 declined from 27,635,000 in 1941 to 26,399,000 in 1942 and trucks from 4,817,200 to 4,677,000. Gasoline consumption per passenger car dropped from 16.03 barrels (673 gallons) in 1941 to 12.94 barrels (543 gallons) in 1942, and consumption per truck dropped from 26.38 barrels (1,108 gallons) to 26.11 barrels (1,097 gallons).

Exports.—Exports of motor fuel were 36,214,000 barrels in 1942 compared with 27,083,000 in 1941.

[2] Subject to revision.

Production.—Motor-fuel output dropped 13 percent—from 701,294,000 barrels in 1941 to 607,011,000 in 1942. The production in 1942 comprised 233,114,000 barrels of straight-run gasoline, 296,928,000 barrels of cracked gasoline, 597,000 barrels of benzol, and 76,372,000 barrels of natural gasoline. Natural gasoline used in producing motor fuel consisted of 56,929,000 barrels blended at refineries, 19,248,000 barrels sold as such, and 195,000 barrels contributed to the increase in motor-fuel stocks.

The straight-run gasoline proportion of total motor fuel produced continued downward, declining from 39.8 percent in 1941 to 38.4 in 1942. The proportion of cracked gasoline also declined from 49.1 percent to 48.9, but natural gasoline increased from 10.6 percent to 12.6. Blended natural gasoline, which increased from 6.8 percent to 9.4, accounted for the rise, as other natural gasoline declined from 3.8 percent to 3.2. Prohibition of the use of benzol in motor fuel is reflected in the decline from 3,435,000 barrels to 597,000. Statistics on disposition of the benzol manufactured have been restricted because of military secrecy. Some of it may have gone into the production of explosives and some into the production of styrene for polymerization with butadiene for the manufacture of synthetic rubber, but a considerable quantity, not included in the above figures, was being used in the production of cumene for aviation gasoline.

Yields.—Gasoline yields, subjected to conflicting forces during 1942, dropped to 39.7 percent from 44.2 percent in 1941. Primarily, the demand for motor fuel was lessened because of the rationing of tires throughout the year and the Nation-wide rationing of gasoline in December. Contrarily, the demand for heating oil and heavy oil fuel was considerably stronger, making it necessary for the usual balance of refinery operations to be modified to produce the minimum requirement of heavy oil without accumulating excessive stocks of gasoline. At the same time, the production of aviation gasoline was one of the most vital functions of the industry, and this kept the yield of gasoline from dropping as low as it would have otherwise.

Yields of 22.2 percent for cracked and of 17.5 percent for straight-run gasoline were both lower than in 1941. The greater loss in cracked gasoline, however, reflected the diversion of cracking stock to fuel-oil uses, notwithstanding the heavy operations to supply base stock for aviation gasoline. The cracked-gasoline yield dropped from its peak of 25.8 percent in December 1941 to 21.3 percent in June 1942; it fluctuated about this point until the end of the year, when it dropped to 20.5 percent in December. The yield of straight-run gasoline dropped only about half as much—from 19.9 percent in December 1941 to 16.7 percent in December 1942.

The greatest drop in yield was in Texas; the Texas Gulf Coast district lost 7.7 percent—from 43.7 percent for 1941 to 36.0 for 1942—and Inland Texas lost 6.1 percent—from 54.6 percent to 48.5. The yield in the Gulf Coast Louisiana district, where emphasis on aviation gasoline production caused the yield of cracked gasoline to rise during the year, experienced the smallest reduction of any district—from 37.7 percent to 37.3. Aviation gasoline production in the East Coast district also, notwithstanding the great need for fuel oil in this district, held the gasoline yield to a loss of only 1 percent—from 38.4 percent to 37.4.

Prices.—The average group 3 refinery price for gasoline in 1942 was 5.91 cents per gallon. Office of Price Administration Schedule 88, signed February 2, provided that prices in effect October 1, 1941, should be ceiling prices for petroleum and its products, except at service stations. As a consequence, the maximum price, which had been 6.375 cents during January and February, was fixed early in March at 6.00 cents—the lowest price prevailing on October 1, 1941. Fluctuations during the balance of the year represent averages between this ceiling price and lower prices for which gasoline sold.

The 50-city service-station average price, which gained 1.84 cents during 1941, was permitted by the Office of Price Administration (see Maximum Price Order 137) to rise another 1.45 cents from January to July 1942, only to be reduced almost 1 cent in August. The year ended with a net gain of .52 cent. Most of the gain represented compensation to the dealers along the East coast for the increased cost of transporting gasoline by tank car instead of by boat, as is normal in peacetimes. The Defense Supplies Corporation assumed 2.5 cents per gallon of this cost in August—the same amount prices had been raised in the East coast area in June—and retail prices were reduced a corresponding sum. General price changes in the East coast area were as follows:

January 23, plus 0.3 cent.
March 27, plus 0.5 cent.
April 30, plus 0.4 cent.
June 29, plus 2.5 cents.
August 5, minus 2.5 cents.

The net change for the East coast cities in general was an increase of 1.2 cents.

Although there were a number of changes during the year in some cities in the Central States, there was little difference in the price at the end of the year from that at the beginning, except for Des Moines, Iowa, and Little Rock, Ark., where prices increased 3 cents. These two increases and a rise of 1.4 cents in St. Louis were responsible principally for an increase of .39 cent in the average price for the cities in the Central States. Even with this rise, these cities had the lowest average price—13.31 cents, ex-tax—of any section of the country.

Decreases in the Rocky Mountain cities brought the average price of 15.15 cents below that of the unchanged Pacific coast area and only slightly above that of the East Coast cities—15.11 cents. Changes were most violent in Salt Lake City, Utah, where cuts reduced the price 4.5 cents in February. One cent of the cut was restored in

Digitized by Google

March, another cent in October, and 1.5 cents more in November making the year-end price only 1 cent less than that at the beginning of the year. One cent of a drop of 3.6 cents in Denver in July was restored in August, leaving the price at the end of the year 2.6 cents less than at the beginning. A loss of 2.0 cents in the price at Butte, Mont., was the only other change in the Rocky Mountain cities included in the 50-city price average.

Twin Falls, Idaho, still had the most costly gasoline for the motorist; the service-station price in that city was 25.6 cents, including 6.6 cents tax, and Boise, Idaho, followed with a price of 24.1 cents. Birmingham, Ala., with a price of 23.5 cents (including 8.5 cents city, State, and Federal taxes) and Charleston, S. C. (with a price of 23.2 cents, including 7.5 cents taxes), were next. The price in Kansas City, Mo., of 15.6 cents was lowest, with the 15.9-cent price in Wichita, Kans., next, followed by St. Louis, Mo. (16.3 cents); all three prices included 4.5 cents taxes.

There were no changes in either State or Federal motor-fuel tax rates during 1942, but the revenue from State gasoline taxes dropped from $950,956,410 in 1941 to $839,457,000 in 1942, and that from Federal gasoline taxes from $371,135,781 to $336,684,645.

Aviation gasoline.—The program for the production of aviation gasoline launched in 1941 was well under way by the end of 1942, when approximately 16 times as much 100-octane gasoline was being produced as at the beginning of 1941. With the largest part of the proposed plants yet unfinished, however, that production was still considerably short of the goal of 250,000 barrels a day.

The change from production of motor fuel to production of high-octane gasoline sufficient to fly the planes of the United States and its allies can be appreciated better when it is realized that iso-octane was merely a laboratory curiosity until a few years ago; that the first output of 100-octane gasoline in commercial quantities was to fill a War Department order in 1934 for 1,000 gallons; that the first commercial catalytic polymerization plant was put in operation in 1937 and the first alkylation plant in 1938—in fact, it was only recently that the chemical world learned that olefins could be combined with parafins, from which discovery the alkylation process developed.

Stocks.—Stocks of finished and unfinished gasoline mounted to a record peak of 108,297,000 barrels on February 28, 1942, then plunged to 73,216,000 barrels on November 30—the lowest point since 1939. They totaled 80,126,000 barrels at the end of the year, compared with 93,844,000 at the end of 1941, although the smaller amount on hand at the end of 1942 represented 63.3 days' supply compared with 55.6 days' supply on hand at the end of 1941.

The Gulf Coast Texas and Louisiana, California, and Inland Louisiana-Arkansas districts had larger stocks at the end of 1942 than at the end of 1941; in fact, stocks in the last district more than doubled during the year. In the East Coast district the stocks dropped 47 percent. Such a severe cut was made possible in this district by pooling stocks and eliminating brand identities, by stopping cross-hauls, and by pooling facilities.

Figure 9 shows the monthly quantities of finished gasoline stocks, in millions of barrels, from January 1, 1940, to December 31, 1942. The figures for days' supply on the chart represent the quantity of

Digitized by Google

finished gasoline on hand at the end of the month, divided by the total demand for the succeeding month.

Figure 9 also shows the stocks of distillate fuel oil for the same years, to stress the contrast in seasonal variations in stocks of the two products. It also shows how distillate fuel-oil stocks, although not declining as greatly as gasoline stocks, were on a considerably lower level throughout most of 1942 than in 1941 despite a demand in 1942 9 percent higher than that in 1941.

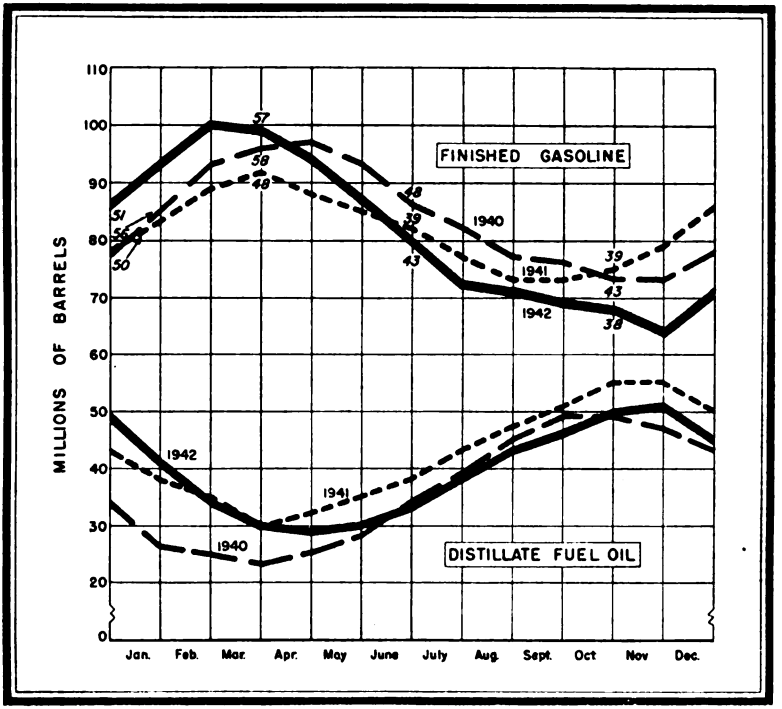

FIGURE 9.—Stocks of finished gasoline in the United States, 1940–42, by months, with figures representing days' supply at certain periods; also stocks of distillate fuel oil, 1940–42, by months.

Production and consumption by States.—Although the relative proportion of gasoline produced by Texas dropped from 32 percent in 1941 to 29 in 1942, its output was almost twice the 15 percent of California, next in importance. Percentages for other important States were: Illinois, 8; Pennsylvania and Indiana, 7 each.

Military requirements caused gasoline consumption in California and Texas to increase in 1942, but tire and rationing restrictions brought material declines for New York, Pennsylvania, and other States. As a result, the States did not follow their usual order of importance. The percentage consumption of the principal States was as follows: California, 9.5; Texas, 7.4; New York, 6.7; Ohio, 6.2; Illinois, 6.0; Pennsylvania, 5.9; Michigan, 5.1.

Distribution.—The methods of moving petroleum products were greatly altered by the war, as much of the burden was shifted from marine to rail transportation. Gasoline shipments by barge and tanker from the Gulf Coast to the East Coast district amounted to only 32,289,000 barrels in 1942 compared with 130,534,000 in 1941. Movement by barge from Texas and Louisiana to points on the Mississippi River, however, increased from 13,736,000 barrels in 1941 to 15,960,000 in 1942.

Pipe-line shipments of motor fuel increased from 111,077,000 barrels in 1941 to 125,341,000 in 1942. Details of pipe-line construction and other developments in transportation appear in the section on Transportation.

KEROSINE AND RANGE OIL

An expected increase in domestic demand for kerosine in 1942 did not materialize, owing to transportation difficulties and rationing of deliveries in some areas; consequently, the 1942 total was practically the same as 1941 requirements. Exports of kerosine declined in 1942; while imports, though of relatively unimportant volume, more than doubled the 1941 total. Lower crude runs to stills and a smaller percentage yield resulted in less kerosine production in 1942 than in 1941. A deficiency in kerosine supply in 1942 due to a lower output resulted in a heavy draft on stocks.

Petroleum refiners produced 7 percent less kerosine in 1942 than in 1941, the output declining from 72,586,000 barrels in 1941 to 67,474,000 in 1942. The yield dropped slightly from 5.2 percent in 1941 to 5.1 percent in 1942; however, lower runs of crude petroleum to stills in 1942 (5 percent under the 1941 volume), tanker transportation difficulties, and the effort of refiners to produce much-needed fuel oils were the principal reasons for the smaller production of kerosine.

[2] New basis to compare with 1942. Monthly figures for 1941 do not include bulk terminal stocks which were not available until December 31, 1941.
[3] Figures not available.

East Coast, Texas Gulf Coast, Louisiana Gulf Coast, and Arkansas and Louisiana Inland, important districts for the production of

Digitized by Google

kerosine, all showed sharp declines in production in 1942 compared with 1941. An exception to this general trend was the Indiana-Illinois refinery district, an area second in national importance as a source of kerosine, where production increased by a third in 1942 over 1941. Gains in kerosine output were also realized in the Appalachian, Oklahoma-Kansas, Texas Inland, and California districts. It should be noted that the Gulf refinery districts, which depend on tankers to transport kerosine to East coast and export markets, showed declines in production, whereas inland districts, which could make rail shipments advantageously to important consuming centers, reported gains in output. In other words, transportation, or the lack of it, largely determined kerosine production in most districts during 1942.

The indicated domestic demand for kerosine in 1942—69,614,000 barrels, calculated from production, change in stocks, exports, and imports—varied little from the 1941 total—69,469,000 barrels. It is believed that the 1942 quantity would have increased at least 5 percent had normal conditions prevailed. The potential market demand was not fully supplied, especially in the North Atlantic Coast area, because of the tanker shortage.

The shrinkage in kerosine exports during present war years continued into 1942, when shipments abroad totaled 2,729,000 barrels compared with 3,221,000 in 1941. Available information for 1941 shows that most of the kerosine shipped abroad went to the United Kingdom (1,941,000 barrels) and to Brazil (223,000 barrels), while in 1942 the United Kingdom and its Dependencies received the larger share—United Kingdom 1,671,000 barrels, Canada 236,000, and Australia 179,000.

Imports of kerosine, though relatively unimportant in volume, increased from 191,000 barrels in 1941 to 418,000 in 1942.

Year-end kerosine stocks for 1941 were revised to include quantities held at bulk terminals. Kerosine in storage at the close of 1942 was 31 percent below the comparative total for 1941—a draft made necessary in order to supplement a curtailed supply resulting from lower refinery production. Kerosine stocks of 10,064,000 barrels in 1942 represented a 40-day supply at the prevailing rate of demand compared with 14,515,000 barrels or a 61-day supply at the close of 1941.

Kerosine inventories on December 31, 1942, were lower in all refinery districts than at the end of 1941 except for the Louisiana Gulf Coast where a gain was indicated. The stock increase in the Louisiana Gulf district (1,290,000 barrels in 1942 compared with 630,000 in 1941) represents a "back-up" of kerosine intended for East coast and other markets due to the shortage of tankers. The pronounced drop in kerosine stocks in the East coast from 6,561,000 barrels at the end of 1941 to 2,853,000 for 1942 was outstanding. Oil companies operating on the Atlantic coast could not obtain their usual supplies of kerosine from the Gulf area because of the tanker situation, so a drastic draft of local stocks was necessary. The extent of the shrinkage in the kerosine inventory on the East coast in 1942 is better illustrated when it is noted that such supplies represented 45 percent of total national stocks in 1941 and only 28 percent in 1942. Higher kerosine production in the Indiana-Illinois district in 1942 and the difficulty of moving the surplus freely to other markets kept

Digitized by Google

up stocks there almost to the 1941 level. Kerosine held in the Texas Gulf coast declined from 3,036,000 barrels in 1941 to 2,456,000 in 1942 as supplies were taken from storage to supplement a declining production. Increased kerosine output in California was not adequate to meet the demand in 1942 so an added quantity was taken from stocks.

Digitized by Google

The Bureau's annual survey of kerosine sales shows deliveries of 68,996,000 barrels in 1941 compared with 67,662,000 in 1940, a gain of 2 percent. The above quantities were divided as follows: Range oil, 41,661,000 barrels in 1941 and 40,715,000 in 1940; tractor fuel, 4,467,000 barrels in 1941 and 4,683,000 in 1940; all other uses, 22,868,000 barrels in 1941 and 22,264,000 in 1940. The range oil market absorbed about 60 percent of total kerosine deliveries for both 1940 and 1941.

Some No. 1 fuel oil, which varies only slightly from kerosine, is also sold for range fuel. This light fuel oil, (4,449,000 barrels in 1941 and 3,977,000 in 1940) must be added to the kerosine reported as range fuel to determine total requirements for range oil. Making this adjustment, total sales of range oil were 46,110,000 barrels in 1941 compared with 44,692,000 in 1940, a gain of 3 percent.

Representative kerosine prices in 1942 changed very little from those prevailing during the last 6 months of 1941. An average monthly price of 4.56 cents a gallon for 41°–43° gravity water-white kerosine at refineries in Oklahoma, starting in June 1941, was maintained until March 4, 1942, when it dropped to an average of 4.44 cents a gallon, a quotation that ruled until the end of the year. The tank-wagon price of kerosine at Chicago (10.3 cents a gallon dating from June 1941) remained unchanged until December 31, 1942, when it increased to 10.6 cents a gallon.

[1] Figures for 1942 by States not yet available.

FUEL OIL

An anticipated large increase in the domestic demand for fuel oils in 1942 was not realized. Rationing of fuel oil in the East coast and Pacific Northwest in 1942, which became necessary because of trans-

Digitized by Google

portation difficulties and military needs, reduced deliveries to a level little above 1941 requirements. The fuel-oil supply in 1941 (production plus imports and transfers from crude) was not only sufficient to cover the domestic demand and export trade, but there was also a surplus to add to stocks. The whole situation was changed in 1942, when imports of fuel oil dropped to half the 1941 quantity and as a result a heavy draft on stocks was made to cover this loss.

The record-breaking fuel-oil requirements of recent years continued into 1942, even though rationing, transportation difficulties, and conversions to other fuels by important consumers all tended to lower deliveries. The indicated domestic demand for fuel oils in 1942—587,785,000 barrels—was 6 percent above the 1941 total—556,246,000 barrels. The domestic market for distillate fuel oils increased from 172,824,000 barrels in 1941 to 184,312,000 barrels in 1942 and for residual grades from 383,422,000 barrels in 1941 to 403,473,000 in 1942. It is noted that the respective percentage gains in domestic demand for distillate fuel oils (7 percent) and residuals (5 percent) were about the same in 1942 as in 1941. These percentage increases are quite different from those in 1940, when an unusual cold spell in the first quarter forced up the requirements for distillates (domestic heating oils) to a 19-percent gain for the year compared with a 5-percent nominal increase for residual grades, and in 1941, when the larger gain (13 percent), was in residual fuel oils, reflecting the demand for fuel by expanding war industries, contrasted with only a 7-percent increase in requirements for distillate grades.

A review of domestic demand statistics for distillate fuel oil, by quarters, reveals an 11-percent increase in the first 3 months, due largely to the requirements for domestic heating oils, as January and February 1942 were considerably colder than the same months in 1941. The percentage gain in the first quarter of 1942 would have been even greater had not mild weather in March reduced the requirements for

Digitized by Google

that month by 1.3 million barrels and lowered the quarterly demand correspondingly. There was a nominal gain of 5 percent in the domestic market for distillates in the second quarter of 1942, followed by a 1-percent decline in the third quarter compared with similar periods of 1941. The drop in the third quarter of 1942 was directly connected with the order preventing the delivery of fuel oil for heating or cooling purposes in District 1 (17 East Coast States and the District of Columbia) during the period August 3–September 15. Deliveries of distillate fuel oil gained 7 percent in the final quarter of 1942, compared with the same period of 1941, even with coupon rationing of light heating oils, which became effective October 1, 1942.

Larger percentage gains (13 percent in the first quarter and 6 percent in the second quarter compared with the respective periods of 1941) were realized in the domestic demand for residual fuel oils than for distillate grades, reflecting the rapidly growing industrial expansion connected with the all-out war program. Restricted deliveries in the July–September period 1942 are evident in the slight loss when the demand is compared with the 1941 market in the same months. There was only a 2-percent gain in domestic demand for heavy fuel oils in the final quarter of 1942 over the 1941 quarter, as many important users of liquid fuel had by that time converted to coal or other sources of energy.

At present, with the Bureau's annual survey of fuel-oil sales incomplete, little is known about the distribution of fuel oil by principal uses in 1942. Preliminary monthly statistics released by the Interstate Commerce Commission give total railroad purchases of 104,072,000 barrels in 1942, a 24-percent gain over 1941 requirements of 83,609,000 barrels. Records of the Bureau of Foreign and Domestic Commerce, United States Department of Commerce, show 25,148,000 barrels of bunker fuel oil delivered to vessels engaged in foreign trade in 1942—a decrease of 11 percent below the 1941 total of 28,337,000 barrels. Many power plants that formerly used fuel oil for producing electric energy converted to coal or other fuels in 1942; this cooperation in the national emergency resulted in considerable saving of fuel oil, the total consumption declining from 20,248,000 barrels in 1941 to 15,300,000 in 1942, a drop of 24 percent. Rationing, temporary stoppages of deliveries, conversions to other fuels, and shortage of spot supplies were factors that probably reduced the consumption of fuel oil by smelters, mines, and manufacturing industries, by oil companies, and in space heating in 1942 compared with 1941.

Figure 11 shows graphically the distribution of fuel-oil sales by principal uses for 1932–41. The volume of yearly sales for each principal use, as indicated by the different columns, is based upon totals derived from the annual fuel-oil survey of the Bureau. Distillate fuel oil, residual fuel oil, and kerosine sold as range oil are included.

[1] Includes Navy grade and crude oil burned as fuel.
[2] Figures for 1942 not yet available.

The overseas market for fuel oil made a net gain in 1942 over 1941, as a large increase in distillate exports was partly counteracted by a loss for residual grades. Total exports of fuel oil (including shipments to noncontiguous Territories of the United States) was 36,248,000 barrels in 1942, a gain of 17 percent over the 1941 total of 31,039,000 barrels. The foreign demand for distillates increased from 16,925,000 barrels in 1941 to 22,716,000 in 1942, a gain of 34 percent, while the market for residuals (totaling 13,532,000 barrels in 1942) was lower by 4 percent than the 1941 quantity of 14,114,000 barrels.

Greatly increased exports of fuel oil went to the United Kingdom and its Dependencies through Lend-Lease arrangements in 1942. Exports of distillate fuel oil to the United Kingdom increased from 7,158,000 barrels in 1941 to 15,714,000 in 1942 and to Canada from 394,000 barrels in 1941 to 493,000 in 1942, while shipments to Australia of 1,002,000 barrels and to New Zealand of 855,000 barrels in 1942 compared with trivial quantities to those countries of the British Empire in 1941. In other words, an export trade in distillate fuel oil, which formerly favored Japan (3,348,000 barrels in 1941) was shifted to our British allies in the South Pacific.

The export market for residual grades of fuel oil was also changed in 1942. Japan and the Philippines were cut off entirely; and unusually large shipments to Chile in 1941 (2,294,000 barrels) slumped to 52,000 barrels in 1942, largely because of the lack of tankers. Exports of residual fuel oil to the United Kingdom increased from 1,542,000 barrels in 1941 to 2,696,000 in 1942.

The production of fuel oil increased 5 percent—from 531,544,000 barrels in 1941 to 555,615,000 in 1942. The gain must be attributed entirely to an increased percentage yield (41.6 percent in 1942 compared with 37.7 percent in 1941), as crude runs to stills were lower by 5 percent in 1942 than in 1941. Unusual conditions prevailing in 1942 enabled refiners to expand the yield of fuel oil to the extent indicated, as motor gasoline was not wanted to the limit of the crude content because of rationing on the East coast (to save gasoline and rubber tires) dating from May 17, 1942, and for the entire country (to save rubber tires) from December 1, 1942. Consequently producers adjusted their runs to make less motor fuel and more of the demand product—fuel oil.

[1] Includes distillate fuel oil, residual fuel oil, and some crude oil burned as fuel.
[2] Figures for 1942 not yet available.

The output of distillate fuel oil, the larger share of which is used for space heating, increased by 4 percent—from 189,177,000 barrels in 1941 to 196,714,000 in 1942. The yield of light fuel oil moved up from 13.4 percent in 1941 to 14.7 percent in 1942. The production of residual fuel oil, in great demand in 1942 because of expanded industrial activities in connection with the war, increased 5 percent—from 342,367,000 barrels in 1941 to 358,901,000 in 1942—and the upward shift in percentage yield (26.9 percent in 1942 compared with 24.3 percent in 1941) was even greater than in the case of light fuel oil.

Digitized by Google

Production of distillate fuel oil increased in all refinery districts except the East Coast and California. The inability to obtain domestic or foreign crude to full requirements on the East coast in 1942, because of transportation difficulties, forced down crude runs materially (161,142,000 barrels in 1942 compared with 217,046,000 in 1941); consequently, there was a decline in the production of distillate fuel oil from 40,827,000 barrels in 1941 to 31,132,000 in 1942, a 24-percent shrinkage. The percentage yield of distillate was stepped up slightly (18.8 percent in 1941 and 19.3 percent in 1942), but this adjustment added very little to the distillate output, considering the much smaller volume of crude processed in 1942. The production of distillate fuel oil in the California district declined from 27,803,000 barrels in 1941 to 24,398,000 in 1942. Although crude runs to stills increased in California in 1942, the percentage yield of distillate was reduced materially (13.0 percent in 1941 and 10.6 percent in 1942) to increase the output of residual grades, which were in great demand. The production of distillate fuel oil increased considerably in the Appalachian, Indiana-Illinois, Oklahoma-Kansas, Texas Inland, Arkansas and Louisiana Inland, and Rocky Mountain districts, all areas either of high consumption, or areas where rail shipment of light fuel oil could be made to important markets to the north and east. Percentage gains in the output of distillate fuel oil were not so high in the Texas and Louisiana Gulf districts, because of the disrupted tanker traffic and the resulting inability to make normal shipments to East coast consuming centers.

Production of residual fuel oil declined in 4 of the 10 refinery districts in 1942 even though the national total was up 5 percent for the year. A 9-percent drop (45,653,000 barrels in 1942 compared with 50,113,000 in 1941) in the output of residuals in the East Coast district was the result of lower crude runs to stills, which even a much higher percentage yield of 28.3 percent in 1942 over 23.1 percent in 1941 could not fully overcome. The production of heavy fuel oils in 1942 was considerably less in the Texas Gulf district, a source of residual fuel oil second only to California in importance, because of a 16-percent decline in runs to stills, an adverse factor that was only partly offset by a slightly higher percentage yield (23.3 percent in 1941 and 24.4 percent in 1942). Lack of an active market for residual fuel oils, lower crude runs, and smaller percentage yields were all reflected in a declining production of heavy fuel oils in the Louisiana Gulf and Arkansas and Louisiana Inland districts in 1942 compared with 1941. Large percentage gains in residual fuel-oil production were realized in the Indiana-Illinois, Oklahoma-Kansas, and Texas Inland districts in 1942, as the fuel oil could be rail-shipped to consumers. High gains in residual output were likewise made in the Appalachian and Rocky Mountain districts, but the quantities produced were relatively unimportant. An 18-percent gain in residual fuel-oil production in California in 1942 (104,255,000 barrels in 1942 compared with 88,411,000 in 1941) was not sufficient to satisfy a very active demand, and the balance was supplied from storage and increased transfers from the crude account.

Digitized by Google

Some crude oils, of little value for refining, are burned directly as fuel. Such crudes are termed "transfers," being changed from the crude to the fuel-oil account on oil-company books. Transfers of fuel oil increased from 15,482,000 barrels in 1941 to 21,779,000 in 1942, a gain of 40 percent. Practically all this increase was limited to residual grades transferred in California (14,658,000 barrels in 1942 compared with 8,874,000 in 1941) where there was a very active market for heavy fuel oils in 1942. Transfers of heavy crudes for areas east of California increased but slightly from 4,095,000 barrels in 1941 to 4,625,000 in 1942. The lower-gravity crudes covered in the above totals, both for California and east of California, are consumed as fuel on leases and in industrial plants. Some light-gravity crudes are used by pipe lines as fuel and are classified as "transfers" to the distillate fuel-oil account in the Bureau's petroleum statistics. Transfers of light crudes were insignificant in California both in 1941 and 1942; however, east of California these transfers increased from 2,383,000 barrels in 1941 to 2,484,000 in 1942.

Disrupted tanker traffic due to sinkings and shifts of boats to military use was reflected in the sharp drop in imports of fuel oils in 1942. Receipts of these products from foreign sources dropped 50 percent—from 42,443,000 barrels in 1941 to 21,073,000 in 1942. In other words, imported fuel oil supplied 8 percent of the domestic demand in 1941 compared with only 4 percent in 1942. The decline in imports of residual fuel oils was more pronounced than for the lighter grades. Receipts of heavy fuel oils from abroad were down by 53 percent from 37,369,000 barrels in 1941 to 17,645,000 in 1942, while distillate imports of 3,428,000 barrels in 1942 were 32 percent below the 1941 total of 5,074,000 barrels.

The large reduction of 26,000,000 barrels in year-end fuel-oil stocks in 1942 compared with 1941 was partly attributable to greatly reduced imports in 1942. In other words, supplies to meet the demand were taken from storage to offset diminishing receipts from foreign sources. Fuel-oil stocks reported for the end of 1942 (106,723,000 barrels) were 19 percent below the total of 132,289,000 barrels for the same period of 1941. The greater part of fuel-oil stocks (79 percent of the 1941 total and 77 percent of the 1942 total) was held at refineries, where year-end inventories decreased by 21 percent—from 105,049,000 barrels in 1941 to 82,620,000 in 1942. Fuel oil held at bulk terminal points decreased by 12 percent—from 27,240,000 barrels in 1941 to 24,103,000 in 1942—and furthermore constituted 23 percent of the 1942 final inventory compared with 21 percent in 1941.

Reviewing light and heavy fuel-oil stocks separately, it is noticed that the shrinkage in volume in 1942 was far more critical in residual grades that for distillates. Heavy fuel oils held at the end of 1942, totaling 61,783,000 barrels, were 26 percent below the comparative 1941 quantity of 82,959,000 barrels, while light fuel oils dropped by only 9 percent—from 49,330,000 barrels in 1941 to a final total of 44,940,000 in 1942. Both light and heavy fuel-oil stocks at refineries and at bulk terminals showed marked declines in 1942 compared with 1941. Refinery stocks of residual fuel oils declined by 27 percent—from 68,727,000 barrels in 1941 to 49,961,000 at the close of 1942—while a 10-percent drop was recorded for distillate grades from 36,322,000 barrels in 1941 to 32,659,000 in 1942. Residuals at refineries made up 83 percent of the total heavy fuel-oil stocks at the

close of 1941, compared with 81 percent of the 1942 quantity. Distillates at bulk terminals constituted 26 percent of the 1941 inventory and 27 percent in 1942, while residual grades carried at such terminals accounted for 17 percent of the heavy fuel-oil storage in 1941 and 19 percent in 1942.

Statistics for fuel-oil stocks show major declines in 1942 for both distillate and residual grades in the East Coast refinery district and also considerable loss for residuals in the California refinery area. Oil d stributors along the Atlantic seaboard, being unable to obtain adequate supplies of fuel oil in 1942 from the Gulf coast and inland areas by tanker, rail, or pipe line, were forced to make an unusual draft on locally held stocks. Over half of the distillate inventory (18,035,000 barrels at the end of 1941 dropped to 8,415,000 during 1942) and two-thirds of the residual supply (9,805,000 barrels in 1941 and 3,613,000 n 1942) were liquidated in 1942. The largest share of residual fuel oils held nationally is stored in California, and there the quantities declined from 53,199,000 barrels at the close of 1941 to 44,231,000 in 1942, a 17-percent shrinkage. The 10-percent drop in distillate stocks in 1942 was a net loss, as outside of the major liquidation in the East Coast and slight declines in the Louisiana Gulf and California refinery districts all other areas showed gains in inventory for the year—a reflection of the lack of normal movement of supplies to markets to the north and east. The principal stock increase for distillates in 1942 was realized in the Texas Gulf district, where the volume rose from 7,801,000 barrels in 1941 to 12,336,000 at the end of 1942, or by 58 percent. Here the tanker shortage prevented an uninterrupted flow of light fuels to the East coast. The decline in heavy fuel-oil stocks most serious in the East coast and California areas, was general for all refinery districts of the country in 1942, except for static supplies in the Appalachian section and a 21-percent gain in the Rocky Mountain States; both regions are unimportant storage areas. Declines in inventory for residual fuel oil in 1942 ranged from a 23-percent reduction in the Louisiana Gulf to a 50-percent drop in the Arkansas and Louisiana inland district.

Tanker shipments of fuel oils from California to the East coast have dwindled sharply under war conditions, and although 203,000 barrels of distillates were shipped in 1941, no movements of fuel oils over this route were reported in 1942. The California refinery district (California, Oregon, Washington, Arizona, and Nevada) makes some overland rail and truck shipments of fuel oils to adjoining States. Distillates in this movement increased from 382,000 barrels in 1941 to 423,000 in 1942, while the volume of residuals handled continued the downward trend of recent years from 130,000 barrels in 1941 to 49,000 in 1942.

Sinkings and diversions of boats for military use in 1942 greatly disrupted the normal flow of fuel oils by tankers from the Gulf coast refinery districts to East Coast markets. The seriousness of this situation is evident when it is noted that the tanker movement (118,543,000 barrels of fuel oil in 1941) dropped to 43,660,000 barrels in 1942—a loss of 63 percent. Gulf tanker shipments of both light and heavy fuel oils to the Atlantic seaboard were down sharply in 1942, movements of distillates declining by 52 percent from 42,620,000 barrels in 1941 to 20,305,000 in 1942, and the traffic in residual grades

Digitized by Google

slumped from 75,923,000 barrels in 1941 to 23,355,000 in 1942—a loss of 69 percent.

With the usual tanker movement of fuel oil from the Gulf coast to Eastern States at a low ebb in 1942, every effort was made to ship needed supplies into the Atlantic area by other means, such as tank cars, barges, and pipe lines. The railroads carried most of this rerouted traffic, hauling 8,329,000 barrels of distillate and 14,740,000 of residual from District 2 to District 1 and 18,951,000 barrels of distillate and 23,058,000 of residual fuel oil from District 3 to District 1 in 1942. Fuel oil moved by barge from the Gulf coast to Mississippi River points, totaling 1,811,000 barrels of light fuel oil and 937,000 of residual grades; possibly some of this oil plus quantities originating in District 2 reached Northern States in District 1 through the Ohio River system for a total of 192,000 barrels of distillate and 230,000 of residual fuel. Tankers and barges operating on the Great Lakes carried 2,344,000 barrels of light grades and 2,233,000 of heavy fuel oils to Eastern States in 1942. Barges following the Gulf coast supplement the fuel-oil supply in the Florida west coast by 655,000 barrels of distillate and 339,000 of residual grades in 1942. Pipe-line deliveries of fuel oil into District 1 appeared in 1942, the quantity being reported as 443,000 barrels of light oils.

Tanker rates on light and heavy fuel oil on the Gulf coast—North Atlantic (not east of New York) route were much higher in 1942 than in 1941, owing to surcharges permitted first by the Maritime Commission and later by the War Shipping Administration "to cover wartime operating expenses." The freight rate on No. 2 fuel oil—57 cents a barrel for November 1941—was dropped to 42 cents a barrel on January 19, 1942. This basic rate held throughout 1942; however, on February 23 the Maritime Commission allowed a surcharge of 37½ percent a barrel to be added to the established rate. The War Shipping Administration advanced the surcharge to 200 percent on April 6, and this charge held for the balance of the year. The Gulf coast—North Atlantic tanker rate for crude and heavy fuel oil (10°–19.9° gravity)—57 cents a barrel for November 1941—was dropped to 48 cents a barrel on January 19, 1942. The surcharges of 37½ percent and 200 percent allowed, respectively, by the Maritime Commission and War Shipping Administration for light fuel oil were likewise granted to tankers for carrying heavy fuel oil on this route.

Representative fuel-oil prices did not change greatly in 1942 compared with 1941, except where higher tanker rates had to be absorbed. The quotation for No. 2 straw fuel oil at refineries in Oklahoma averaged 3.82 cents a gallon in 1942 compared with 3.69 cents in 1941, and important mark-ups were seen in oils for ships' bunkers at New York where tanker rates were involved, Bunker C advancing from an average of $1.34 a barrel in 1941 to $1.61 in 1942 and Diesel grade going from $1.99 a barrel to $2.57. Bunker C at Gulf ports at 89 cents a barrel in 1942 varied little from the 1941 average quotation of 87 cents a barrel; however, Diesel oil for bunkers in this area rose by 8 cents in 1942 to $1.64 average per barrel. An active market for heavy fuel oils in California in 1942 was shown in a 5-cent increase to an average of 85 cents a barrel for Bunker C, but the price of Diesel fuel at $1.41 a barrel was only 1 cent above the 1940 average.

An average price for No. 2 straw fuel oil at refineries in Oklahoma—3.88 cents a gallon for November 1941—prevailed through January

Digitized by Google

1942. There was a transitional price of 3.87 cents a gallon in February 1942, and this settled to 3.86 by March, which average quotation held until late in August. A lower average price of 3.74 cents a gallon was quoted for September and October, followed by a slight rise to 3.75 cents in November and a slump to 3.65 cents a gallon for the final month of 1942.

[1] Platt's Oil Price Handbook.

The average price of Bunker C at New York dropped from $1.41 a barrel in December 1941 to $1.37 in January and $1.35 in February 1942, indicating lower tanker rates on the Gulf Coast—North Atlantic route. Advancing tanker rates caused the Bunker C average price at New York to rise gradually to $1.80 a barrel in May; this "high" held through July, after which the quotation for heavy bunkers settled to $1.66 a barrel in August and to $1.65 from September to the end of 1942. The average quotation for Bunker C at Gulf ports—90 cents a barrel for July 1941—remained through July 1942, when there was a gradual reduction to 89 cents in August, 88 cents in September and October, 86 cents in November, and finally 85 cents a barrel in December 1942. Bunker C in California sold for 88 cents a barrel average from June 1941 through May 1942, then dropped to 84 cents a barrel for the remaining months of the year.

Digitized by Google

The cost of Diesel fuel for bunkers at New York was responsive to rising Gulf-to-New York tanker rates. An average quotation of $2.15 a barrel, starting in September 1941, prevailed through February 1942, when advancing tanker costs gradually pushed up the price to a "high" of $3.24 a barrel in July 1942. August brought a drop to $2.82 and then to $2.78 for the final months of the year. The price of Diesel for bunkers at Gulf ports—$1.73 a barrel in November 1941—was maintained through February 1942, when there was a drop to $1.64 in March and to $1.62 in April; this average quotation remained in force until December 1942, when the price rose to $1.65 a barrel. Ships paid $1.40 a barrel for Diesel fuel in California from July 1941 through May 1942, when there was an advance to $1.43 a barrel; this higher quotation was maintained for the balance of the year.

The Bureau of Labor Statistics, United States Department of Labor, releases monthly data covering the retail prices of various fuels in many cities of the country. These publications show that the retail price of representative No. 2 domestic heating oil at Chicago—7.65 cents a gallon, effective in October 1941—was maintained at the same level throughout 1943. The consumer's price for No. 2 fuel oil at New York—7.27 cents a gallon ruling in November 1941—remained unchanged through March 1942. After this date rapidly rising freight costs for tanker and rail shipments pushed up the retail quotation of No. 2 to 9.99 cents a gallon in July. Price reductions on gasoline and fuel oils along the Atlantic coast, effective August 5, 1942, as ordered by the Office of Price Administration made possible by subsidies to dealers from the Defense Supplies Corporation to cover mounting transportation and other costs, forced down the retail cost of No. 2 fuel oil to 8.79 cents a gallon for the remaining months of the year.

LUBRICATING OIL

The fewer miles traveled by motor vehicles in 1942 because of tire and gasoline rationing and the restriction of speed to 35 miles per hour were shown by a decline in the domestic consumption of lubricants to 29,018,000 barrels compared with 30,255,000 used in 1941. Production decreased to 38,626,000 barrels from 39,539,000 in 1941, and exports were 8,311,000 barrels compared with 9,924,000 in 1941. Stocks increased to 9,424,000 barrels at the end of 1942 compared with 8,127,000 at the end of 1941.

Automotive use of lubricants dropped from 11,679,000 barrels in 1941 to 8,704,000 in 1942. This, principally, was attributable to the reduction in mileage traveled by passenger cars, but lower consumption of oil because of slower speeds was also a factor. A tendency contributing slightly in the opposite direction was the older average age of vehicles.

Consumption of lubricants for industrial uses rose to 20,314,000 barrels compared with 18,576,000 in 1941 and 13,760,000 in 1940. This gain indicates not only the rise in industrial activity and military requirements but also new uses for lubricating oils.

[1] Subject to revision. [2] Figures not available.

The Texas Gulf Coast district maintained the lead in production of lubricating oil, its 9,356,000 barrels being 24.2 percent of the total. The relative standing of the East Coast district continued its downward trend, declining to 20.2 percent from 21.8 in 1941. California dropped to 6.9 percent compared with 8.2 in 1941 and 9.1 in 1940, the year of its highest relative production. The Inland Louisiana-Arkansas district had the greatest increase in production—from 1.7 percent of the total in 1941 to 3.2 in 1942. The Oklahoma, Kansas, Missouri district followed, with an increase from 10.1 percent to 11.1.

Lubricating-oil stocks of 9,424,000 barrels at the end of 1942 were the highest for any year end since 1931. They increased in all of the districts except Texas Inland, the gain of 34 percent in the Texas Gulf Coast district being the largest.

Domestic demand for lubricating oil, 1938–42

Military necessities have brought radical changes in the manufacture of lubricating oils. The attempt to restrict lubricants used for military purposes to as few grades as possible requires that all those lubricants be of high grade. Not only must they meet the ordinary and heavy-duty needs of tanks, trucks, light automotive equipment, and airplanes, but they must function within the wide range of conditions under which military vehicles operate. Airplane oils must withstand temperatures which, within moments, may change from the warmth of the tropics to the cold of the stratosphere; trucks and tanks serve both in the sand and heat of the desert and in the ice and cold of the Arctic. The two principal qualities needed for such lubricants are high viscosity index and low pour point.

Vital to production of the superoils required for such service is solvent dewaxing, a method developed principally since 1937. Before the use of this process only Pennsylvania-Grade oils could serve for heavy-duty purposes, but by using solvents to dissolve the wax and asphalt, a high-viscosity-index lubricant can be produced from western and Gulf coast crudes.

But even our best mineral oils are not sufficient in themselves for the severe conditions they sometimes meet. Qualities must be built into them to permit them to lubricate properly at extreme temperatures. This is done by adding agents—"additives"—that have special qualities, such as oiliness, antioxidation qualities, detergent or cleansing qualities, and fluidity at low temperatures, besides inhibitors to counteract certain detrimental effects of the additives.

Scarcity of chemicals necessitated a restricted use of many additives in oils for nonmilitary vehicles. Chlorine was eliminated wherever possible, and cresol, detergent, and detergent-disperser type additives and extreme-pressure lubricants were designated "not for passenger cars." Use for nonmilitary services of pour-point depressants and oxidation inhibitor-type additives was reduced as much as possible.

Prices of lubricating oils, in general, clung close to their maximums permitted by the Office of Price Administration. Pennsylvania neutrals, however, were an exception. The lowered mileage of passenger automobiles, as well as the slower speeds traveled, has reduced considerably the demand for neutrals from which these lighter oils are made. At the same time, military officials have been demanding all the Pennsylvania-Grade heavy-duty oil that can be made; in consequence, the production of bright stock, from which these heavy-duty oils are compounded, has caused accumulation of the neutrals

Digitized by Google

necessarily produced along with the bright stocks. Stocks of neutrals from Pennsylvania-Grade crude totaled 526,000 barrels on December 31, 1942, compared with 140,000 barrels on the same date in 1941.

Average monthly refinery prices of five selected grades of lubricating oil in the United States, 1941–42, in cents per gallon [1]

[1] National Petroleum News.

The maximum price for the Pennsylvania neutral quoted in the accompanying table was set at 33 cents a gallon on August 4, 1941, by the Office of Price Administration and Civilian Supplies. This constituted a reduction, as the oil had sold as high as 40 cents, and no sales thereafter were for less than the ceiling until the middle of August 1942. After that the price declined throughout the balance of the year, reaching a low of 23 cents in December.

It should be kept in mind that the trend of automobile lubricants has been toward a lighter oil and that with the resumption of peace and normal automobile travel, conditions existing just before the war when neutrals were more popular probably will return. Plans should be made to store excess high-grade neutrals in preparation for that time.

A new Federal excise tax on lubricating oils raised the tax from 4½ cents per gallon to 6 cents, effective November 1, 1942, and the Office of Price Administration provided that the 1½-cent additional tax might be passed to the consumer by adding 1 cent to each sale of 5 quarts or less or the full tax to any sale of more than that quantity.

OTHER PRODUCTS

Wax.—Domestic demand for paraffin wax reached a new peak of 546,313,000 pounds in 1942, compared with 523,965,000 in 1941. Exports, however, dropped to 153,410,000 pounds, from 213,075,000

Digitized by Google

in 1941, making total demand somewhat less than in 1941. Imports dropped to 9,749,000 pounds from 16,542,000, and stocks at the end of the year were 85,400,000 pounds compared with 74,814,000 at the end of 1941.

Production—700,560,000 pounds—was 30,520,000 pounds higher than the 1941 output of 670,040,000 pounds. A gain of 140 percent in the production in Inland Texas was the largest relative increase, but it still left that district with less than 0.5 percent of the total. The only districts where decreases occurred were the East Coast and Louisiana Gulf Coast.

Prices remained throughout the year at the maximum permitted by the Office of Price Administration, effective December 1, 1941. These ranged from 4.25 cents per pound of 122°–124° melting point to 5.50 cents for crude scale wax of 132° and higher and from 5.0 cents for 120°–122° to 10.5 cents for 149°–151° fully refined wax. A change, however, was made in the method of calculating the amount paid. The above prices originally were f. o. b. seller's shipping point, with the freight equalized from certain basing points. An amendment, in force January 30, 1942, made the effective prices those above plus actual shipping costs.

Coke.—Coke output came under close supervision of the Petroleum Administration for War in 1942. The tendency to neglect coke production in favor of fuel oil, when prices for the latter increased, led to a request by the Administrator that certain refineries raise their output. Use of coke was restricted to essential war requirements, principally for the manufacture of electrodes needed for the production of aluminum and other vital commodities.

[1] Subject to revision. [2] Less than 0.1 percent. [3] Figures not available.

Output of coke in 1942 amounted to 1,338,400 tons compared with 1,648,800 in 1941. Production declined in all districts except Gulf Coast Louisiana, where the output amounted to 16,200 tons—the first material production since 1938. The Indiana, Illinois, Kentucky, etc., district supplied 63 percent of the output.

Digitized by Google

Domestic demand, restricted to essential war needs, amounted to 1,004,400 tons compared with 1,628,700 in 1941. Exports were 328,200 tons compared with 279,100 in 1941. The 233,800 tons of stocks were 5,800 above the record year-end low of 1941.

Asphalt and road oil.—Domestic demand for asphalt was 6,460,200 short tons compared with 6,451,800 in 1941. Production was 6,296,500 tons compared with 6,557,600 in 1941; imports declined from 158,300 tons to 142,500 and exports from 274,100 tons to 171,800. Stocks were 411,000 tons at the end of 1942 compared with 604,000 at the end of 1941.

Domestic demand for road oil declined from 8,980,000 barrels in 1941 to 8,484,000 in 1941. Production dropped from 9,149,000 barrels to 8,039,000 and stocks from 793,000 barrels to 348,000.

Detailed statistics on asphalt and road oil appear in the chapter on Asphalt and Related Bitumens.

Still gas.—Production of still gas in 1942 totaled 275,054 million cubic feet (equivalent, 76,404,000 barrels) compared with 300,074 million cubic feet in 1941. Of the latter, 283,021 million cubic feet (94 percent) were used as refinery fuel, which, in terms of British thermal units, constituted more than half of all the heat used at refineries.

The Texas Gulf Coast district continued to lead in the production of still gas in 1942, with the Indiana, Illinois, Kentucky, etc., and East Coast districts following in order.

Production of still gas in the United States, 1940–42, by districts

[1] Subject to revision.

Miscellaneous oils.—Domestic demand for miscellaneous oils amounted to 14,225,000 barrels in 1942 compared with 11,862,000 in 1941.

Production totaled 7,795,000 barrels compared with 6,266,000 in 1941. Of the production in 1941, 4,739,000 barrels were liquefied petroleum gas, and an additional 6,281,000 barrels of this product were transferred from natural gasoline. Detailed analysis of production is not available for 1942, but transfers from natural gasoline in that year amounted to 7,195,000 barrels. Gains in the production of petrolatum, absorption oil, medicinal oil, and specialities in 1941 over 1940 ranged from 7 percent to 40 percent.

WORLD PRODUCTION [2]

War damages and dislocation of ocean shipping resulted in a 7-percent decrease in the world production of crude petroleum, if numerous unofficial statistics and estimates can be considered reliable. The outstanding decreases were in Venezuela, the Netherlands East Indies, and the U. S. S. R. The United States, largest producer in the world, showed only a 1-percent decline from 1941 to 1942.

The Western Hemisphere supplied 80 percent of the world output in 1941 and 81 percent in 1942. Lack of shipping caused American and British-Netherlands corporations operating in Venezuela and Colombia to reduce their output. In Peru and Ecuador, however, the foreign companies were able to increase their production. In Argentina the Government enterprise (Y. P. F.) accounted principally for an 8-percent increase from 1941 to 1942.

A decline in exports from 15.8 million barrels in 1941 to 6 3 million barrels in 1942 caused Mexican production to decrease 17 percent, in spite of increased domestic consumption of mineral oils. Export sales were confined to the Western Hemisphere in 1942; and shipping difficulties did not permit the United States and Cuba, the principal purchasers, to take their normal amounts of Mexican oil in 1942.

Canada maintained its 1941 level of production in 1942; and Trinidad apparently increased its output.

[1] Approximate production. Data derived in part from World Petroleum, vol. 12, No. 2, February 1941, pp. 20–21, and vol. 13, No. 3, March 1942, p. 88.
[2] Includes U. S. S. R. fields in Asia, other than Sakhalin.
[3] Approximate production.
[4] Unoccupied China.
[5] Exclusive of U. S. S. R. fields in Asia, other than Sakhalin, which are included with U. S. S. R. in Europe.

Reliable information on petroleum production in Europe is extremely meager. Rumania maintained its level of output from 1941 to 1942. The U. S. S. R. apparently experienced a 12-percent loss owing to military operations on the north side of the Caucasus Mountains. Hungary presumably increased its petroleum production.

Digitized by Google

Increased military activity in Egypt and Libya and improvement in the supply of tankers enabled Iran, Bahrein Island, and Iraq to enlarge their output of petroleum from 1941 to 1942. On the other hand, deliberate sabotage by retreating Allied armies apparently reduced petroleum production in the Netherlands East Indies, Sarawak and Brunei, and Burma beyond the possibility of full rehabilitation by the invading Japanese.

FOREIGN TRADE [3]

IMPORTS

Imports of mineral oils, crude and refined, into continental United States decreased 64 percent from 1941 to 1942. They constituted 2 percent of the total new supply in continental United States in 1942, compared with 6 percent in 1941.

Mineral oils, crude and refined, imported into continental United States, 1941–42, by months [1]

[1] Imports of crude as reported to Bureau of Mines; imports of refined products compiled from data of Department of Commerce; figures may differ slightly from those used throughout other sections of this report.
[2] Subject to revision.

Crude petroleum, residual fuel oil, and distillate fuel oil made up 96 percent of the total imports in 1941 and 95 percent in 1942. Venezuela supplied 74 percent of the crude petroleum imported in 1941 and 55 percent in 1942; Mexico 19 percent in 1941 and 27 percent in 1942; and Colombia 6 percent in 1941 and 18 percent in 1942. Of the residual fuel oil imported in 1941, the Netherlands West Indies furnished 74 percent, Venezuela 22 percent, and Mexico 32 percent. In 1942 the Netherlands West Indies shipped 90 percent

[3] By A. H. Redfield, Petroleum Economics Division, Bureau of Mines.

Digitized by Google

and Venezuela 5 percent of the imported fuel oil. Of the distillate fuel oil imported the Netherlands West Indies sent 33 percent in 1941 and 53 percent in 1942; Venezuela 24 percent in 1941 and 25 percent in 1942; and Mexico 41 percent in 1941 and 18 percent in 1942.

Receipts of foreign crude petroleum were 76 percent lower in 1942 than in 1941. Imports of residual fuel oil declined 53 percent from 1941 to 1942 and of distillate fuel oil 32 percent.

EXPORTS

Continental United States increased its net exports of mineral oils from 11,688,000 barrels in 1941 to 86,055,000 barrels in 1942. This was due principally to a shift from net imports of crude petroleum amounting to 17,368,000 barrels in 1941 to net exports of 21,537,000 barrels in 1942; and to a decrease in net imports of residual fuel oil from 23,255,000 barrels in 1941 to 4,113,000 barrels in 1942. Net exports of motor fuel and of distillate fuel oil were greater in 1942 than in 1941.

In absolute amounts, exports and Territorial shipments of mineral oils, both crude and refined, were 11 percent larger in 1942 than in 1941. The principal gains were in outward shipments of motor fuel and of distillate fuel oil. On the other hand, less kerosine, residual fuel oil, and lubricating oil were exported and shipped to noncontiguous Territories in 1942 than in 1941. Outward shipments of crude petroleum were virtually unchanged from 1941 to 1942.

INTERCOASTAL SHIPMENTS [4]

Submarine attacks on shipping and diversion of tankers to wartime routes reduced shipments of mineral oils from Gulf coast ports to the East coast by 71 percent. Crude petroleum underwent the greatest decrease—79 percent. Intercoastal shipments of gasoline declined 75 percent; kerosene 65 percent; distillate fuel oil 52 percent; and residual fuel oil 69 percent.

Gasoline was the largest single item in these intercoastal shipments in 1942, constituting 26 percent of the whole. Crude petroleum was 25 percent, residual fuel oil 19 percent, and distillate fuel oil 16 percent.

Mineral oils, crude and refined, shipped from Gulf coast to East coast ports of the United States, 1941–42, by classes

[Thousands of barrels]

SUMMARY

The natural-gas industry attained new peaks in 1942 as it responded to heavy demands from war industries and to expanding civilian requirements. Final figures for the year are not yet available, hence the following summary is largely estimated.

Marketed production of natural gas in 1942 totaled 3,055 billion cubic feet—9 percent above the peak of 2,813 billion reported in 1941 (see fig. 1). All the major classes of consumption increased except field use, which declined 1 percent, and gas used in carbon-black manufacture, which fell 8 percent. Increased field use for gas-lift operations in a few States did not quite counterbalance a recession in drilling operations in the country as a whole, and the slump in the rubber industry which furnishes the principal market for carbon black slowed production of that commodity. The largest percentage increase over 1941 was in fuel used at petroleum refineries, which was 25 percent above the 1941 figure; substitution of natural gas for fuel in place of fuel oil and possibly still gas is the probable cause of this increase. Gas used at portland-cement plants gained 19 percent and gas used for miscellaneous industrial purposes 15 percent. Both classes contributed heavily to war requirements. Natural gas is especially adapted for furnishing controlled heat for the manufacture of precision parts for guns, planes, tanks, and ships. An estimated 25 percent of total deliveries is reported to have been used by war industries in 1942.

[1] Subject to revision.
[2] Federal Power Commission.
[3] Chapters on Cement in Minerals Yearbook.
[4] Exclusive of oil- and gas-field operators.

The average value of natural gas at the wells in 1942 was 5.1 cents a thousand cubic feet, compared with 4.9 cents in 1941. Increased production in the eastern fields where higher prices prevail and a strengthening of the price in Texas, which produced over a third of the total output in the United States, contributed to the 0.2-cent gain.

The average value at points of consumption was 23.3 cents in 1942 compared with 22.1 cents in 1941. A gain of 1.1 cents in the average price of industrial gas and an increase in the relative proportion of the higher-priced domestic-commercial gas outweighed declines in the average prices of domestic and commercial gas. The total value of natural gas consumed in the United States in 1942 was $710,338,000—15 percent over the peak of $620,038,000 reported in 1941.

Digitized by Google

Gas treated for natural gasoline approximated 3,000 billion cubic feet in 1942, compared with 2,763 billion in 1941. The proportion of total consumption was 98 percent in 1942 and 99 percent in 1941.

Exports to Mexico were 8,670 million cubic feet in 1942—18 percent over the 1941 figure. Mixed gas exported to Canada contained

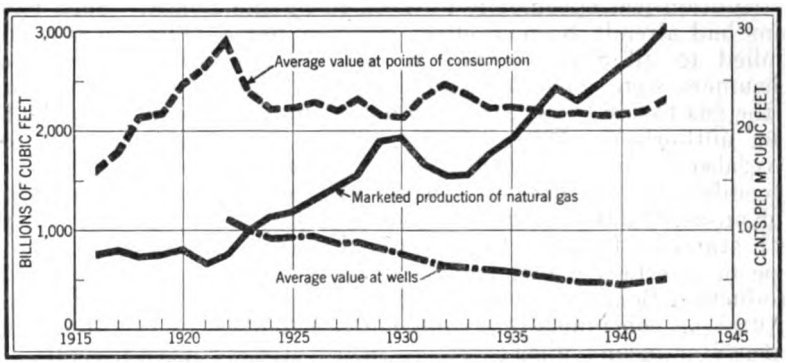

FIGURE 1.—Production and value of natural gas in the United States, 1916-42.

130 million cubic feet of natural gas compared with 121 million in 1941.

Consumers using natural gas in the United States in 1942 totaled 10,865,000—3 percent more than in 1941.

LEGISLATIVE AND LEGAL REVIEW

Conservation continued to be a paramount consideration in 1942, not only as regards the long-term program of producing more efficiently and with less waste, but the conservation of manpower and equipment as well.

The Federal Power Commission was given a wider scope of authority early in the year, and a number of orders were issued regulating the activities of gas companies. Existing pipe-line companies were ordered to file applications with the Commission by May 8, 1942, to obtain certificates of necessity to remain in business and were required to obtain authority before building new lines or changing old ones. In general, the policy was to cut down competition between companies and to avoid extending lines into territory already supplied with gas or to districts where other fuels are readily available.

The Office of Petroleum Administration for War issued a number of orders with regard to drilling. Order M–68 permitting only one well drilled to each 640 acres was modified on February 12 to allow more drilling in New York, Pennsylvania, West Virginia, Ohio, and Kentucky. This order was revised further on June 20 to permit drilling gas wells on 40-acre tracts in Missouri and parts of Oklahoma and Texas. Drilling in the Hugoton field in Kansas and Oklahoma was suspended by Order M–68–6 issued on September 3. More than 20 wells in the field were reported to have no pipe-line connections, and it was decided that no more drilling was necessary until the available production was utilized.

In September the War Production Board ordered that the line of the Panhandle Eastern Pipe Line Co. be connected to that of the Ohio Fuel Gas Co. in Ohio, to assure a supply of Texas gas to supplement that from the eastern fields, preventing a possible shortage in the area supplied by the latter company. Effective November 30, deliveries to nonresidential consumers were suspended unless such distribution was specifically authorized by the Board. Such restrictions had already been in effect in a few States, but the new ruling applied to all States. Sales of heating equipment to residential consumers were curtailed and prohibited in places where delivery of the gas to residential, commercial, or industrial consumers had not been authorized. When shortages were imminent, gas companies were also required to curtail deliveries to domestic consumers. On December 12, gas deliveries were ordered suspended in some parts of Kansas, Oklahoma, and Missouri to plants which were equipped with stand-by facilities for using coal, and to all refineries with any type of alternative fuel facilities. Early in January 1943 the War Production Board was empowered to cut off either manufactured- or natural-gas consumers that could convert to other fuels without undue expense or inconvenience.

The Office of Price Administration placed a price ceiling on both wet and dry natural gas, effective October 7, 1942, except for rates charged by public utilities or others specifically excluded from the order. The price could be retroactive to May 11.

GROSS PRODUCTION

In the absence of final figures on marketed output, gross production of natural gas in 1942 has not been estimated. The 1941 figure is estimated at 4,103,500 million cubic feet or 11 percent more than the 1940 total. Production from gas wells increased 9 percent to 2,279,590 million cubic feet and from oil wells 14 percent to 1,823,910 million. There were sharp decreases in New York and Mississippi, where gas fields are becoming depleted and oil fields are small. Most of the other States made gains in output from both gas and oil wells. Decreased production from oil wells was noted in Illinois, Michigan, Oklahoma, Pennsylvania, and West Virginia.

Repressuring operations are gaining rapidly in importance; 644,379 million cubic feet of gas were returned to formations in 1941 compared with 362,916 million in 1940. Notable gains were made in Louisiana and Texas, where the cycle process is being extensively used in condensate fields; for example, repressuring in Texas rose from 294,000 million cubic feet in 1940 to 527,159 million in 1941 and in Louisiana from 21,000 million to 56,008 million. Repressuring was reported in Michigan for the first time in 1941. Arkansas, Kansas, and Oklahoma were the only States that reported declines from the 1940 volumes.

[1] Marketed production plus quantities used in repressuring, stored in ground, lost and wasted (see footnote 2).

[2] Includes gas (mostly residue gas) blown to the air and transportation losses but does not include direct waste on producing properties, except where data are available.

[3] Produced approximately as follows: 373 million cubic feet in Oklahoma, 525 million in Texas, and 264 million in Kansas.

[4] Produced approximately as follows: 183 million cubic feet in West Virginia and 300 million in Kentucky.

[5] Produced approximately as follows: 109 million cubic feet in Pennsylvania and 305 million in New York.

[6] Produced approximately as follows: 397 million cubic feet in Kentucky, 2,216 million in West Virginia, and 1,093 million in Ohio.

[7] Produced approximately as follows: 178 million cubic feet in Kentucky, 424 million in West Virginia, and 1,121 million in Pennsylvania.

[8] Produced approximately as follows: 148 million cubic feet in Kentucky, 7 million in Pennsylvania, and 271 million in West Virginia.

[9] North Dakota, South Dakota, Tennessee, Utah, Virginia, and Washington.

[10] Subject to revision.

[11] Produced approximately as follows: 267 million cubic feet in Kentucky, and 173 million in West Virginia.

[12] Produced approximately as follows: 334 million cubic feet in New York, and 6 million in Pennsylvania.

[13] Produced approximately as follows: 1,865 million cubic feet in West Virginia, 962 million in Ohio, 320 million in Kentucky, and 19 million in Pennsylvania.

[14] Produced approximately as follows: 1,251 million cubic feet in Pennsylvania, 1,110 million in West Virginia, and 480 million in Kentucky.

[15] Produced approximately as follows: 341 million cubic feet in West Virginia, 215 million in Kentucky, and 23 million in Pennsylvania.

Digitized by Google

Gas storage in depleted fields has been successful in a number of States, and that method of building up a reserve to be drawn upon in times of peak demand is gaining importance. In 1941, 16,251 million cubic feet of natural gas were reported stored in 10 States compared with 14,995 million stored in 8 States in 1940 and 8,032 million stored in 6 States in 1939.

Reported losses and waste of natural gas totaled 630,212 million cubic feet in 1941—a 4-percent decline from 1940 and 7 percent below 1939. This record is creditable but leaves room for improvement, even though much of the total waste is unavoidable.

MARKETED PRODUCTION

The marketed production of natural gas in 1941 was 2,812,658 million cubic feet—a 6-percent gain over the 1940 record of 2,660,222 million cubic feet. Decreases were reported in Mississippi, Missouri, New York, and Oklahoma. All other States important in gas output made increases. The major producing States having the largest were: Kansas, 23 percent; Louisiana, 18; West Virginia, 10; California, 7; and Texas, 2. Texas retained first place in amount produced, and Louisiana displaced California in second place.

West Virginia produced 57 percent, Louisiana 45 percent, and Texas 19 percent over State requirements; the surplus was piped to other States and some Texas gas went to Mexico.

The value of natural gas at the wells turned upward in 1941 after dropping steadily for many years. The average was 4.9 cents a thousand cubic feet compared with 4.5 cents in 1940. The average value at points of consumption was 22.1 cents in 1941 compared with 21.7 cents in 1940.

Natural gas produced in the United States and delivered to consumers, 1937–41, by States, in millions of cubic feet

[5] Includes 6,191,000 M cubic feet piped to Mexico.

WELLS

Producing gas wells, as of December 31, 1941, numbered 55,500—3 percent, more than the 53,880 reported at the end of 1940. As 2,911 wells were drilled during the year, it would appear that 1,291 were abandoned. Actually abandonments probably were fewer, for some of the productive wells reported are old ones that have been reconditioned or deepened.

During 1942 2,597 wells were drilled—11 percent less than the number of completions in 1941. An increased demand for production usually results in greater drilling activity; but difficulty in obtaining materials, Government restrictions, and shortages of manpower retarded operations during the year.

TECHNOLOGIC DEVELOPMENTS

When the shortage of materials became serious because of the war, renewed efforts were made to find substitutes and additional sources of various commodities. New experiments were made with natural gas and methods found by which its various hydrocarbons could be separated.

The components of natural gas have been found to be valuable in the manufacture of a wide range of war products, from nylon, ammonia, and synthetic rubber to an anaesthetic that is being used increasingly because of its harmless effects.

The necessity for conserving cargo space has brought dehydrated foods to the fore. Natural gas has been found an ideal source of heat to be used in drying fruits, vegetables, and even shrimp. Several California firms are producing dehydrated foods by the ton, and the industry is becoming important in the State. Some food experts believe that the general public will use dehydrated products increasingly in the near future.

REVIEW OF FIELD DEVELOPMENTS, BY STATES

Arkansas.—Joe W. Kimzey, State geologist, has submitted information taken from the records of the Arkansas State Department of Revenues regarding developments in Arkansas.

All the gas-well drilling reported was in the northwest gas fields. One well was drilled in Crawford County to a depth of 5,104 feet, two in Franklin County to 5,755 and 2,900 feet, respectively, and one in Logan County to 2,690 feet. All were dry holes and abandoned. In Pope County a well was drilled to a total depth of 2,830 feet in sec. 22, T. 10 N., R. 21 W. Gas was found in the second sand with an initial production of 17,263,000 cubic feet and in the third sand with initial production of 9,562,000 cubic feet.

Digitized by Google

Arkansas produced 29,560 million cubic feet of gas during 1942—a 20-percent increase over the 24,617 million cubic feet reported in 1941. The dry-gas fields in the northwestern area produced 5,367 million cubic feet—16 percent less than the 1941 output. In the southern area production increased 33 percent over the 1941 total to 24,193 million cubic feet. Union County ranked first in output with 10,085 million cubic feet, Columbia was second with 9,080 million, and Miller third with 4,440 million. Johnson, with 2,439 million, was the only county in the northwest field that produced over a million cubic feet of gas.

California.—Demands for low-gravity oils to meet war requirements centered activity in California during 1942 in the relatively shallow heavy-oil zones in the South Joaquin Valley area. Such drilling contributed virtually nothing to natural-gas reserves. Information on gas developments in the State during the year is taken from a report from E. F. McNaughton, California Railroad Commission.

Steady drilling in the proved area of the Wilmington field of the Los Angeles Basin resulted incidentally in the formation of secondary gas caps and a correspondingly higher gas : oil ratio in the field as a whole, so that more gas was available.

The Bowerbank gas field was discovered in the South Joaquin Valley area when an existing well was redrilled. Other wells drilled in the vicinity were failures. The Roberts Island dry-gas field, which apparently was not very large, was the only important discovery during the year. The proved area of the Riverdale gas field was extended 2¼ miles northeast, resulting in increased activity in that area. The northern boundary of the Raisin City gas field was determined by an unsuccessful completion.

One of the main gas lines from the San Joaquin Valley to the San Francisco area was converted into an oil line in May 1942. To replace this, a 22-inch line was built to connect the metropolitan area with the Rio Vista gas field. The new line, with rearranged facilities of other lines, made available 140 to 150 million cubic feet of gas over the 180 million formerly transported daily by the converted line. Sharp gains in consumption, caused by war production and additional requirements by civilian and military users, made this additional supply necessary. Only about 100 million cubic feet were brought daily from the oil fields, which formerly furnished most of the total supply. Another line was built to connect the Rio Vista field with other areas formerly served with casinghead gas.

Dry gas from the Buttonwillow and Trico fields was run through a line that formerly carried casinghead gas. Because dry gas has a lower heating value than casinghead gas, the California Railroad Commission established an automatic heating-value clause to adjust consumer rates according to the quality of gas served. This provision is in general effect, except for interruptible surplus service.

The nearly depleted Playa del Rey field was tested for underground storage in 1942, and at the end of the year construction was progressing on permanent compressor facilities. It is estimated that 3 billion cubic feet of gas can be stored in the field. Between 15 and 20 million cubic feet probably will be withdrawn daily. The field lies near the heart of the Los Angeles area where peak demand occurs and will furnish an easily accessible auxiliary supply.

Digitized by Google

Another supply of gas will be stored in a water-seal gas holder with a capacity of 10 million cubic feet, which was completed and placed in service late in 1942 in Los Angeles.

The commission made a survey during the year to determine the daily peak demand for and availability of gas to assure war industries and essential civilian services an uninterrupted supply. It was concluded that demands, though greatly augmented, could be met with existing facilities. Available reserves, as of July 1, 1942, were estimated at 11,007 billion cubic feet and unavailable reserves at 1,456 billion. It was thought that the daily peak demand would total 1,635 million cubic feet. Production for the first half of the year was 206,645 million cubic feet, of which 203,410 were utilized and 3,235 blown to the air. Comparable figures for 1941 were 191,858, 184,554, and 7,304 million, respectively. Figures for the latter half of the year are not available. Dry-gas production in 1942 was 104,867 million cubic feet compared with 36,450 in 1941. The sharp gain was due principally to pipe-line connections with gas fields to replace casinghead gas. Another factor was Government restrictions on production in fields having high gas: oil ratios, so that withdrawals could not be varied to meet fluctuating demands, which forced distributors to depend on dry-gas supplies.

Gas sales totaled 264,444 million cubic feet in 1942 compared with 232,751 in 1941—a 14-percent gain.

Colorado.—Little drilling was done in Colorado during 1942. One well was completed in the Powder Wash field with an initial production of 11,660,000 cubic feet, and the field was extended ½ mile northeast. One well was deepened and the deepening of another started. An exploratory well at Douglas Creek found less than 1,000,000 cubic feet of gas in the basal Dakota sand at 4,433–35 feet. Drilling was continued to the Weber quartzite in search for oil, but work was suspended for the winter at a depth of 7,313 feet. Information regarding developments in Colorado was supplied by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo.

Hiawatha field, with a 37-percent increase, and Powder Wash field, with a 136-percent increase, supplied 76 percent of the total output of the State. All of the fields increased production except Berthoud and Garcia. Gross output, by fields, in millions of cubic feet, follows: Hiawatha, 2,727.1; Powder Wash, 1,125.6; Wilson Creek, 303.0; Thornburg, 167.5; Berthoud, 42.4; Garcia, 16.5; and Craig, 4.9.

Marketed production in 1942 totaled 4,029.5 million cubic feet—a gain of about 49 percent over the 2,713.0 million marketed in 1941. Gross production was 4,387.0 million cubic feet—52 percent over the 1941 figure and twice the amount reported in 1940. It is estimated that 53.8 million cubic feet were used in the field and 303.7 million lost. Of the latter amount, 291.2 million were in the Wilson Creek field, which does not yet market gas.

Illinois.—A. H. Bell, geologist, and C. W. Carter, assistant geologist, Illinois Geological Survey, have reported natural-gas developments in Illinois during 1942.

The Russellville gas field had 5 gas completions within proved territory in 1942, making a total of 53 in the district. The average initial production of the new wells was approximately 2 million cubic

Digitized by Google

feet daily. Three of the new wells produced from the Bridgeport and two from the Buchanan sand. At the end of the year the field had 270 acres proved in the Bridgeport sand and 1,600 in the Buchanan. Marketed production from the district was 1,472 million cubic feet compared with 863 million in 1941.

The Ayers field, covering 335 acres, had one gas completion in 1942, making a total of eight wells in the area. Gas comes from the Bethel sandstone at a depth of about 950 feet. Production was virtually the same as in 1941.

Daily average production of casinghead gas from the Louden oil field in 1942 was estimated at 8.4 billion cubic feet, with an average daily output at the end of the year approximating 20 million cubic feet. Comparable figures for 1941 were 13.7 billion and 36 million. The greater portion of the gas was treated for natural gasoline, and 6 million cubic feet of the residue gas were injected into the producing sands daily. A pipe-line company was furnished with residue gas to supply St. Elmo, Brownstown, and Vandalia. The same company also received 50 thousand cubic feet daily from a well in the field that produced from the basal Pennsylvanian sandstone.

Gas produced from the Salem oil field was estimated at 23.7 billion cubic feet in 1942, with an average daily output of 63 million cubic feet compared with 35.4 billion and 82 million, in 1941. Four gasoline plants processed an average of 49.8 million cubic feet a day. One company returned approximately 5 million cubic feet of residue gas daily to the producing sand, and another supplied residue gas to Salem, Centralia, and Mount Vernon; the quantity approximated 800,000 cubic feet daily at the end of the year.

A small amount of residue gas from a gasoline plant near Hoodville in Hamilton County, that began operation in December, was injected into the producing sands through several input wells, marking the beginning of a large-scale pressure-maintenance system in that area.

The New Harmony Consolidated oil field had an estimated production of 8.7 billion cubic feet of casinghead gas in 1942, with daily production approximating 21 million cubic feet at the end of the year. About 1.5 million cubic feet of residue gas from a plant that began operations in the field in July were returned to the producing sands daily during the latter half of the year.

The Albion pool, Edwards County, supplied brick plants at Albion with an estimated 100 million cubic feet of gas until the end of the first quarter of 1942, when the plants closed. The field produced approximately 2 million cubic feet of gas daily.

It is estimated that 84.4 billion cubic feet of gas were produced from oil fields discovered after January 1, 1937, but a large part was burned in flares.

Marketed output of natural gas in Illinois in 1942, exclusive of field uses, totaled 2,573.4 million cubic feet, a 51-percent gain over the 1,699.4 million cubic feet produced in 1941.

Indiana.—Ralph E. Esarey, State geologist, and Dr. George V. Cohee, assistant State geologist, report that no large gas reserves were discovered in Indiana during 1942. Only 21 gas wells were drilled during the year—35 less than in 1941 and all in previously discovered fields. Their total initial production was 11,148,500 cubic feet.

Total marketed production of all fields during 1942 was 1,627.3 million cubic feet, 20 percent over the 1,355 million reported in 1941.

Digitized by Google

This gain was due largely to a 29-percent increase in the Rockport field, which supplied approximately 37 percent of the total output, and to increased production from the Unionville field. Production from the major fields, in millions of cubic feet, was as follows: Rockport, 594.3; Unionville, 239.9; Greensburg, 210.8; Glendale-Hudsonville, 157.0; North Glendale, 102.4; and Laconio (Harrison), 100.0.

Gas from the Griffin oil field, Posey and Gibson Counties, is being used for repressuring the field, after being treated for natural gasoline at a plant that began operations in August 1942 on the Illinois side of the Wabash River. By March 1943 over 1.5 million cubic feet were being injected into the producing sands daily through 14 input wells. Gas from the same plant is also being used to repressure the Waltersburg sand in the Ribeyre Island portion of the New Harmony field through four input wells.

Kansas.—The State had 88 gas-well completions in 1942 compared with 102 in 1941. Information on gas developments was supplied by Charles P. Kaiser, geologist, Kansas Geological Survey.

The Hugoton field was an outstanding exception to the sharp decline in drilling in most of the major fields in the western part of the State. There were 21 completions in Hugoton in 1942 compared with 11 in 1941. The new wells had a daily potential of 324.4 million cubic feet, and production in the field increased from 36.4 billion cubic feet in 1941 to 41.4 billion in 1942. Much of the drilling was in Grant County near the carbon-black plant at Ryus. In all, 299,919 million cubic feet had been drawn from the Hugoton field by the end of 1942.

McLouth, in Jefferson and Leavenworth Counties, eastern Kansas, was the field of greatest activity in 1942. There were 44 gas-well completions compared with 39 in 1941. A total of 89 gas wells has been drilled in the field since production was begun in 1941. The output was 4,438.9 million cubic feet in 1942 compared with 1,667 million in 1941.

Completions in the Cunningham-Cairo field in Kingman and Pratt Counties dropped from 16 in 1941 (with a total daily potential of 190.5 million cubic feet) to 4 in 1942 (with a total daily potential of 41.4 million).

Other completions in the western area were two in the Peace Creek oil pool in western Reno County and two in the Medicine Lodge pool.

Thirteen wells were drilled in eastern Kansas. Completions were made in Allen, Chautauqua, Douglas, Elk, Franklin, Greenwood, Johnson, and Neosho Counties.

Two discovery wells were completed in western Kansas—one in the Deerhead pool, Barber County, and one in the Belpre pool, Edwards County. The first had an initial potential of 4 million cubic feet from the Viola limestone, the second 25 million from the Lansing-Kansas City group of sands.

Production by the major fields, in billions of cubic feet, was: Hugoton, 41.4; Otis, 11.0; Medicine Lodge, 9.9; McLouth, 4.4; Burrton, 3.9; Thurber, 3.3; and Lyons, 0.6. The output of most of the large fields increased, whereas that in some of the smaller ones declined. Western Kansas supplied the major part of a total daily potential of 615.5 million cubic feet. The total for 1941 was 825.4 million cubic feet.

Digitized by Google

It is estimated that marketed production in Kansas in 1942 was 103 billion cubic feet compared with 99 billion in 1941.

Kentucky.—During 1942 210 gas wells were drilled in Kentucky, or about 10 percent below the high mark of 1941, according to information supplied by Mrs. Louise B. Freeman, assistant State geologist, Kentucky Department of Mines and Minerals. Completions in the four most active counties were: Pike, 74; Floyd, 51; Knott, 37; and Martin, 25. Of the total output, 65 percent in Pike, 66 in Floyd, 79 in Knott, and 53 in Martin County came from the Devonian-Mississippian black shales.

Clay and Jackson Counties were next in rank, with 8 wells each. In Jackson County 24 wells with an average rock pressure of 140 pounds have been drilled since development started there in 1934. The gas is found at 1,100 to 1,200 feet depth and comes from the Niagara dolomite (Coniferous) sand; output has been greatly increased since it has been found that the wells respond to acidizing. The field has become important, even though the gas is not being marketed.

Five wells were drilled during the year in the Johnson County field, 4 miles west of Paintsville; Knox and Magoffin Counties each had one well.

There was little gas development in western Kentucky during 1942.

Louisiana.—Drilling in Louisiana resulted in 88 gas completions in 1942—a 21-percent decline from 1941. Northern Louisiana had 50 completions, with 373,160 acres proved for gas; Southern Louisiana had 38 completions, with 40,885 proved acres.

Only one-fourth of the 48 wildcat wells drilled in the Gulf Coast area were successful, and of the 12 only 2 were completed as gas wells. Distillate fields led in importance in the area.

A well blew out in Arcadia Parish in October 1942 and was still out of control at the end of the year in spite of all efforts to check it. In December it was flowing 523 barrels of oil and distillate and 49,220,000 cubic feet of gas at a depth of 10,447 feet. A relief well was being drilled and was down to 10,025 feet as the year ended.

One of the most important discoveries of 1942 was a well 3 miles southwest of Krotz Springs in the Branch area of St. Landry Parish, which opened a new distillate pool in December. At 11,398 feet it was the deepest wildcat drilled in that area but was plugged back to 9,327 feet.

Distillate was found in the extreme southern part of Bayou Sale field in St. Mary Parish; it comes from a new sand located at 10,703 feet. The well was drilled to a depth of 12,000 feet.

Development in Northern Louisiana shifted in 1942 from the Wilcox sand, which predominated in 1941, to the deeper Pettit and Smackover limes. The Monroe field was the most active in the State, with 30 completions, followed by the North Lisbon in Claiborne Parish and the Nebo-Hemphill field in LaSalle, with 4 completions each.

The following data were furnished by H. W. Bell, Division of Minerals, Louisiana Department of Conservation. The total natural-gas production in Louisiana in 1942 was 669,136 million cubic feet, of which 463,695 million (69 percent) were from gas wells and 205,441 million (31 percent) from oil wells. Northern Louisiana produced 388,274 million cubic feet of dry gas and 46,131 million of casinghead gas. Southern Louisiana produced 75,421 million cubic feet of dry gas and 159,310 million of casinghead gas. The Monroe field re-

Digitized by Google

mained the major gas-producing area in Louisiana, with an output of 217,915 million cubic feet, or 47 percent of the total dry-gas production. The field comprises 61 percent of the gas acreage of the State. Parishes having largest output were: Union, 100,084 million cubic feet; Morehouse, 68,425; Webster, 55,890; Ouachita, 49,439; Caddo, 29,912; and Bossier, 28,501. There are 36 parishes in the State having dry-gas production from about 70 gas fields.

Michigan.—The following information on natural-gas developments in Michigan in 1942 was furnished by F. R. Frye, petroleum engineer, Michigan Department of Conservation.

In all, 74 gas wells were completed in 1942 compared with 97 in 1941. Previously discovered gas fields in Clare and Osceola Counties were the main points of interest during the year. Of the 74 wells drilled, 30 were in the Marion field, where about 9,500 acres are proved, and 11 in the Evart field, extending the proved acreage there to about 2,100 acres.

Four wells were drilled in the Riverside pool in Missaukee County, the proved acreage approximating 2,240 acres. Two discovery wells were completed, but no additional drilling was done in their vicinity up to the close of the year. The Don Rayburn-Mee No. 1 well in sec. 4, T. 19 N., R. 3 E., was drilled in Arenac County in search for oil. It was put down to the Dundee sand, which was dry, then plugged back to the Berea sand, where it was finished as a gas well, having 300,000 cubic feet initial production and a pressure of 830 pounds. The new pool was tentatively called the North Adams. In December, the Belvidere Oil Co. completed its State No. 1 well for gas at a depth of 1,489 feet in the Michigan Stray sand in Fork Township, Mecosta County. The initial open flow was 1,010,000 cubic feet and the well-head pressure over 500 pounds a square inch.

A desulfurization plant was built in the Riverside pool and put in operation in December 1942, to bring the sulfur content of the gas within the requirements of the Public Service Commission. This field is the first where it has been found necessary to process gas from the Michigan Stray sand.

A main gas-transmission line, started in 1941 from the Ohio State line to Saginaw and Kalamazoo, was completed in 1942. A request for permission to build a line from the Austin gas pool, which is being used for storage, to the Six Lakes pool was denied by the War Production Board.

Reported production of natural gas reached an all-time high of 17,749 million cubic feet—approximately 17 percent over the 1941 figure of 15,092 million.

Mississippi.—H. M. Morse, supervisor of the Mississippi State Oil and Gas Board, reports that the Jackson field continued to be the main source of natural gas in Mississippi in 1942. The field had 23 gas wells producing during the year. One new well was completed in 1942; none was abandoned.

Production in the field has declined steadily since 1939, when the peak of 15,233 million cubic feet was attained. The output in 1942 was 2,084 million—85 percent less than the peak year and 46 percent less than the 1941 figure.

Large quantities of gas are used for pumping in the Tinsley, Vaughan-Pickens, and Pickens-Sharpsburg oil fields, and a smaller amount was burned in flares.

Digitized by Google

The gas:oil ratio is so low in the Cary oil field that the gas is not used.

Missouri.—Gas completions in Missouri dropped from 18 in 1941 to 7 in 1942. Wells drilled in 1942 were as follows: Bates County, 2, initial open flow 550,000 cubic feet; Caldwell County, 1, initial open flow 200,000 cubic feet; and Platte County, 4, initial open flow 400,000 cubic feet.

As yet no arrangements have been made to utilize the gas from the Polo field in Caldwell County, discovered in 1940.

The above information was supplied by Frank C. Greene, geologist, Missouri Geological Survey.

Montana.—Wells drilled in Montana totaled 69 in 1942 compared with 59 in 1941. Data on natural-gas developments were taken from a report by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo.

Bowdoin and Cedar Creek fields reported 56 of the gas completions, but all had small initial production. The other 13 were in the Cut Bank, Kevin-Sunburst, and Hardin fields. Total daily initial production of the new wells was 87,265,000 cubic feet. The old fields in Montana need continual drilling to compensate for declines in pressure and volume. Some of the old wells were cleaned, repaired, or deepened to augment production. Two minor discoveries were made, one on the Fred and George Creek nose in T. 37 N., R. 2 E., and one at Conrad Butte in T. 29. N., R. 1 W., but they will not be used unless considerable quantities of gas are developed.

Bowes, Dry Creek, and Kevin-Sunburst were the only fields that did not have increased production in 1942. The Cut Bank field, which produced 45 percent of the total output, made a 21-percent gain over 1941, and Cedar Creek, next in rank, gained 4 percent. The following table shows production in Montana, by fields.

Natural gas produced in Montana in 1942, by fields, in thousands of cubic feet

Field	Marketed gas production	Gas used for repressuring	Estimated field use	Estimated waste
Bowdoin	3,137,543			3,000
Bowes	477,361			500
Box Elder	484,147			500
Cedar Creek	6,890,539			8,000
Cut Bank	13,554,401		400,000	50,000
Devon	389,518			10
Dry Creek	1,017,969			1,000
Hardin	89,518			600
Haystack Butte	91,636			10
Kevin-Sunburst	2,731,448	22,820	600,000	15,000
Whitlash	1,046,139			50
	29,910,219	22,820	1,000,000	78,670

Gross production in the State in 1942 was 31,012 million cubic feet—13 percent over the 27,483 million produced in 1941 and 21 percent over the 1940 total. Marketed production totaled 29,910 million cubic feet—an increase of 2,591 million (9 percent) over that of 1941. The Kevin-Sunburst field was the only area in which repressuring was reported, 23 million cubic feet being used for that purpose in 1942 compared with 7 million in 1941. Field use consumed 1,000

Digitized by Google

million compared with 21 million the previous year, and losses were cut from 137 million in 1941 to 79 million in 1942. The amount of gas treated for natural gasoline exceeded the 1941 figure by 12 percent. A plant at Cut Bank treated 11,891 million cubic feet to produce 2,684,000 gallons of natural gasoline, 201,000 of propane, and 1,548,000 of butane, and in the Dry Creek field another plant processed 128 million cubic feet to produce 70,000 gallons of natural gasoline.

The Cut Bank and Kevin-Sunburst areas were connected by a 25-mile line built during the year.

New Mexico.—Of the 12 gas wells drilled in New Mexico in 1942, 8 were in the southeastern and 4 in the northwestern part of the State. This compares with 13 in the southeastern and 6 in the northwestern areas in 1941. The new wells had total initial productions of 107,010,000 cubic feet and 35,720,000 cubic feet, respectively. Three San Juan County wells found gas in the Dakota sand on the Barker Creek structure.

According to information supplied by Foster Morrell, acting supervisor, Geological Survey, United States Department of the Interior, Roswell, N. Mex., natural-gasoline plants treated 103,704 million cubic feet of natural gas in 1942—a decrease of over 5 percent from the 1941 throughput. Domestic, commercial, and industrial consumers in Lea County used over 42 percent (44,132 million cubic feet) of the gas after it was treated for natural gasoline. In Eddy County 75 million cubic feet of residue gas were marketed. The total of these two amounts represents a 21-percent gain over the 36,472 million marketed in 1941. Gas used for gas lift and field consumption and vented without treatment for natural gasoline amounted to 47,299 million cubic feet in 1942—approximately 2½ times the 19,289 million similarly accounted for in 1941. Total production in the southeastern area probably increased more than 20 percent over the 1941 output.

In the northwestern area, 4,022 million cubic feet of gas were used by domestic, commercial, and industrial consumers, leaving 125 million for fuel and wastage. Production increased 13 percent over the 1941 figure.

New York.—The total output of wells drilled in New York in 1942 continued the decline that began 5 years ago. C. A. Hartnagel, State geologist, reports that unless new reserves are found the total production of the State will drop to the comparatively low level maintained before gas was discovered in the Oriskany sand. Known reserves are being rapidly depleted, and efforts to find new ones have met little success.

Out of 26 wells (most of them exploratory) drilled to the Oriskany sand in 1942, only 6 were productive, compared with 18 out of 42 in 1941. Tompkins County was the most active district in 1942, but efforts to develop the pool resulted in only 2 small producers. Steuben County had only 4 successful completions in 1942, compared with 14 in 1941. Allegany County had 13 gas completions in 1940, 2 in 1941, and none in 1942. Five dry holes drilled in Allegany County in 1942 were over 4,700 feet deep and in Steuben County 4 were over 5,000 feet. New wells were located as follows: Tompkins County, 11; Steuben County, 9; Allegany County, 6.

No important developments occurred in any of the proved Oriskany pools, and the discovery of new supplies of gas appears discouraging.

Digitized by Google

Only two or three wells were added in the small Trenton limestone field in Oswego and Oneida Counties, and the output continued to be negligible. A few wells were added to the large number of producers in the old Medina fields of western New York.

North Dakota.—According to Wilson M. Laird, State geologist, no new natural-gas developments took place in North Dakota during 1942. The only well drilled was in Oliver County in search for oil, and it was dry.

The pipe line that supplies gas in eastern Montana and a number of communities in the Dakotas took 121,955,000 cubic feet of gas from eight wells in the Cedar Creek field in the southwestern part of the State. Apparently the gas was used as an auxiliary supply, for none was taken between May and September, when demand for domestic fuel is comparatively light.

Ohio.—The following data were taken from reports by Kenneth Cottingham, chief geologist, Ohio Fuel Gas Co.

Under adverse conditions resulting from the war, the total number of gas wells drilled in Ohio in 1942 was 33 percent less than the record of 1941 and below the number of completions in any year since 1938. The daily average initial production of the new wells was 5 percent less than that of wells drilled in 1941. It is estimated that one-tenth of the State acreage was under lease to oil and gas operators at the beginning of 1942, but many of the leases were said to have been surrendered toward the end of the year.

The Clinton sand remains the chief source of gas in the State, although completions in that formation were 16 percent and the average open-flow capacity 17 percent less than in 1941. No significant new areas were discovered, and no important additions were made to the proved acreage. Little drilling was exploratory. A well drilled in Bearfield Township, Perry County, gave every indication that a small Clinton pool had been discovered. It had an initial daily open flow of 1,390,000 cubic feet, but two wells drilled nearby were dry. In Plain Township, Wayne County, a small pool was opened, and about 500 acres were proved. A discovery well having an initial volume of 4,500,000 cubic feet was completed near the end of the year in the southwestern part of Wellington Township, Lorain County, at a depth of about 2,400 feet. The pool is thought to comprise about 350 acres.

Little was done toward finding new production in the Oriskany sand, though it is thought to have possibilities. One well completed in Liberty Township and four in Wheeling Township, Guernsey County, north of the old Cambridge field, averaged 3,300 feet in depth and 1,456,000 cubic feet initial daily open flow. About 1,500 acres were proved in the Oriskany sand, but it is thought that the field will be small. In Mayfield Township, Cuyahoga County, four wells with an average initial open flow of about 2,327,000 cubic feet were drilled to a depth of 1,890 feet. In Richfield Township, Summit County, a well was developed with an initial volume of 238,000 cubic feet. Two attempts to find gas in the Oriskany sand in Meigsville Township, Morgan County, and in Adams Township, Washington County, resulted in dry holes.

No unusually deep drilling was done during 1942. The deepest gas well was in Fairfield Township, Tuscarawas County; production in this well was found in the Clinton sand at 5,313 feet. The initial

Digitized by Google

volume was 898,000 cubic feet. Another deep test, probably to the Trenton sand, drilling at 6,850 feet found the Clinton sand 18 feet thick at a depth of 5,398 feet, but it was dry.

The productive sands, number of wells drilled, and average initial production per well, in thousands of cubic feet, were as follows: Clinton, 273 wells with 904 thousand cubic feet average initial volume; Shallow, 90 with 351; Berea, 86 with 168; Oriskany, 10 with 1,682; Ohio shale, 7 with 131; and Newburg, 5 with 783.

A well in York Township, Morgan County, proved to be the most productive of the year. It was 4,261 feet deep and had an initial daily open flow of 11,700,000 cubic feet and an initial rock pressure of 1,030 pounds.

Gas wells were drilled in 30 counties in 1942 compared with 35 in 1941. Morgan County, not included in the 10 most active counties in 1941, ranked first in number of gas completion in 1942; Meigs held second place, with 21 fewer wells drilled; Medina, eighth in rank in 1941, was third, with 10 more wells drilled; Licking, first in 1941, dropped to fourth place, with 78 fewer completions. Counties of greatest activity and number of wells drilled in 1942 were: Morgan, 43; Meigs, 42; Medina, 33; Muskingum, 33; Licking, 24; Washington, 24; Tuscarawas, 23; and Wayne, 23.

Oklahoma.—Gas completions in Oklahoma dropped 42 percent or from about 175 in 1941 to 102 in 1942. Much of the drilling was in old areas of proved production. No notable new fields were discovered. Wildcatting increased 26 percent, but very little new production was found. The wildcat wells completed for gas were located as follows: Hughes County, 2; Pittsburg, 2; and Comanche, LeFlore, McIntosh, Okfuskee, Pottawatomie, Sequoyah, and Texas, 1 each.

Activity in the Hugoton gas field was stopped during the year by order of the Petroleum Administration for War. The Oklahoma part of the field, which covers most of Texas County, is the largest known gas reserve in the State. It is estimated to have a 33-year supply of gas, as measured by the present rate of total production of all fields. The field is as yet virtually untouched, only about 0.3 percent of the estimated original reserve having been produced.

According to information supplied by Dan O. Howard, petroleum engineer, Oklahoma Corporation Commission, natural-gas output gained 6 percent in 1942 compared with 1941. Total production amounted to 276,532 million cubic feet. Oil wells produced 151,064 million (55 percent) and gas wells 125,468 million (45 percent). The daily average production approximated 758 million cubic feet. Ninety-five percent of the homes in the State are built to use only natural gas as fuel, and each household averages 95,000 cubic feet of gas a year.

Exports of natural gas to the north and east of Oklahoma continued the increase that began in 1938, largely because of increased industrial demand. A total of 50 billion cubic feet—30.6 percent of the total amount available in the State for domestic and industrial consumption—was transported to other States during 1942.

Carbon-black plants in Oklahoma utilized approximately 10 billion cubic feet of gas during 1942. One chemical plant is proving that natural gas has growing importance in the manufacture of such by-products as formaldehyde, methanol, and related chemicals obtained by direct oxidation of the gas.

Digitized by Google

The commission is intensifying its efforts to prevent waste of gas in the oil fields and to regulate production in the gas fields to insure maximum recovery.

Pennsylvania.—Information regarding natural-gas developments in Pennsylvania was supplied by J. G. Montgomery, vice president, United Natural Gas Co. The shallow gas fields were the focal point of gas developments in 1942, as was true in 1941. Some drilling is still being done in the deep fields; but production continues to decline, and the fields appear to be almost exhausted. During the year 738 shallow wells were drilled; 80 percent produced gas.

New developments in the southwestern part of the State have proved approximately 2,200 acres in the Armbrust pool, Hempfield Township, Westmoreland County. Total initial volume of the 75 productive wells in the pool was about 48 million cubic feet a day. Nine wells in the Big Injun sand of western Fayette and eastern Greene Counties had average initial capacities of over 1 million cubic feet a day, and 16 wells in Greene, Allegheny, Indiana, Washington, Armstrong, and Westmoreland Counties approximated the same amount. Jefferson County (with 135 wells drilled), Clarion (with 91), Elk (with 63), and McKean (with 49), were the most active of the central Pennsylvania counties in 1942. Others having developments were Clearfield, Forest, Mercer, Venango, and Warren, where a total of 46 wells was drilled. Highland and Ridgway Townships, Elk County, Jenks Township, Forest County, Oliver and Polk Townships, Jefferson County, and Bell Township, Clearfield County, each had a well with an initial open-flow capacity of over 1 million cubic feet.

Very little new production was found in the deep fields. In the Fayette County field, four wells were completed in the Summit gas pool; their initial open flow capacity was 141,000 cubic feet, 11,875,000 cubic feet, 11,700,000 cubic feet, and 1,500,000 cubic feet. Gas was found in the fractured Onondaga chert and the underlying Oriskany sandstone. The complex faulting of this field makes drilling difficult. In Potter County a well in Bingham Township having an initial open-flow capacity of 185,000 cubic feet a day and one in Wharton Township having a capacity of 600,000 cubic feet a day were completed. The first well in Pennsylvania to produce gas in commercial quantities from the Newburg member of the Lockport dolomite was drilled in Worth Township, Mercer County. It had an initial capacity of 159,000 cubic feet a day.

Unsuccessful deep tests included two each in Potter, Tioga, and Lawrence Counties and one each in Greene, Beaver, and Westermoreland Counties. In Tioga County the Salina series below the Oriskany and Helderberg sands, in Lawrence and Mercer Counties the Lockport dolomite, in Westmoreland County the Helderberg below the Oriskany sand, and in Erie County the Trenton limestone were all found to be unproductive.

The area where no Oriskany sand was encountered was extended further by the two wells drilled in Mercer County.

Much more natural gas was produced in Pennsylvania during 1942 than in previous years. The increase is entirely in the shallow fields, as production from the deep fields continued to decline. The output from the deep fields has dropped steadily, as the following figures show: 2,500 million cubic feet in 1942, 3,750 million in 1941, 6,500

556250—43——73

Digitized by Google

million in 1940, and 30,000 million in 1939—a 92-percent decline between 1939 and 1942. Figures of production from the shallow fields are not available.

South Dakota.—The status of natural gas in South Dakota remained unchanged in 1942, according to E. P. Rothrock, State geologist. Gas from a few artesian wells at Pierre and Fort Pierre and on a few ranches near the Missouri River continued to be used.

A drilling program on large acreages that have been under lease for over a year is promised in the spring of 1943, but there was no activity during 1942.

Tennessee.—According to Kendall E. Born, associate geologist, Tennessee Department of Conservation, production of natural gas in Tennessee comes from the Sunbright oil field in Morgan County and the Jamestown gas field in Fentress County. Gas is found in the Mississippian limestone in the former and the Trenton limestone in the latter county; both formations are fissured and fractured.

No production figures are available for the Sunbright field for 1942; in the Jamestown field 7,378,000 cubic feet of gas were marketed from six wells.

Texas.—In all, 238 gas wells were drilled in Texas in 1942 compared with 294 in 1941—a decline of 19 percent.

The Texas Panhandle and Texas Gulf districts are the only two areas in which the reported number of gas completions gained over those in 1941. Completions in the Panhandle increased 18 percent, or from 49 in 1941 to 58 in 1942. Known gas areas in the Panhandle were enlarged by completions in Hansford and Sherman Counties. The Texas Gulf district had 38 completions in 1942—2 more than were reported for the previous year.

Less than half as many gas wells were drilled in 1942 as in 1941 in the North Central and Southwest districts and less than one-third as many in East Texas. West Texas had only three less in 1942 than in 1941.

Wildcatting was active in North Central Texas, but only 1 of the 105 exploratory wells drilled in the district was reported as a gas well. A discovery well was drilled in the Gulf Coast region in Matagorda County north of the Bay City field and 3 were drilled in West Texas. A new gas field was opened in Victoria County in Southwest Texas on November 1 by a well that had an initial production of 162 million cubic feet. One successful wildcat well was drilled in Jim Wells County and one in Dimmitt County. The new Sarco gas field in Goliad County, Southwest Texas, was opened by a well 9 miles southeast of Goliad. The well had an open flow of 180 million cubic feet of gas and 50 barrels of distillate. As the year closed, a wildcat well was making distillate and gas at a depth of 8,542 feet, on a drill-stem test in Starr County, 1½ miles from production. It is one of the deepest active operations in the Rio Grande Valley.

Data on natural-gas operations have been supplied by Jack K. Baumel, Railroad Commission of Texas. The total production of natural gas in 1942 was 1,917 billion cubic feet—an increase of 5.5 percent over the 1,817 billion produced in 1941. Gas lines already in operation were adequate for transmitting gas to meet sharply increased demands, so that there was no problem of transportation, such as confronted the petroleum industry. Deliveries to pipe lines

Digitized by Google

increased from 65,973 million cubic feet in January 1942 to 71,768 million in December.

Of the total output, 1,271 billion cubic feet (66 percent) were sweet gas, 238 billion (13 percent) sour gas, and 408 billion (21 percent) casinghead gas. These figures indicate a 13-percent increase over 1941 in the production of sweet gas, whereas sour gas decreased 7 and casinghead gas 6 percent.

Cycling- and repressuring-plant operations increased 2 percent—from 570 billion cubic feet in 1941 to 580 billion in 1942. This was an 82-percent gain over the 1940 figure. Gas processed for natural gasoline totaled 904 billion cubic feet, a 4-percent decline from the 945 billion treated in 1941. Carbon-black plants used 295 billion cubic feet of gas in 1942, 10 percent less than the 329 billion used in 1941. Gas vented to the air decreased 19 percent in 1942 compared with 1941.

Utah.—Gross production of natural gas in Utah was 4,390 million cubic feet in 1942—7 percent less than the 4,724 million reported in 1941 and only 1 percent over the output in 1940. Only 6 million cubic feet of the total output in 1942 were not marketed, 1 million being used in the field and 5 million lost. There were 20 million not marketed in 1941 and 45 million in 1940, according to figures furnished by L. G. Snow, acting supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo.

A plant near Farnham utilized 149 million cubic feet of carbon dioxide from the Farnham dome in the manufacture of dry ice, compared with 102 million in 1941.

No drilling was done in the State during the year.

Virginia.—A report from William M. McGill, assistant State geologist, Virginia Conservation Commission, gives information regarding natural-gas developments in Virginia. Gas in commercial quantities was discovered in the State in a well completed in June 1931. Five other wells, four of which produced gas, were drilled between that time and February 1940. Gas from the wells was turned into a 4-inch line in March 1938 to supply Bristol, Va., and Bristol, Tenn. A well was completed in 1941 in the Lower Mississippian limestone of Washington County at a depth of 3,910 feet. Another in the northwestern part of Rockingham County was shut down after gas was found at 2,992 feet in the Devonian sand.

A small gas well was completed in January 1942 on the Early Grove anticline in Scott County. It found gas in the Little Valley limestone (Lower Mississippian) at a depth of 3,670 feet. The initial daily production was 139,000 cubic feet and the initial pressure 1,300 pounds. It was stated later that it would yield 125,000 cubic feet daily and that the pressure had built up. A second well is reported to have been drilled in the Ewing district, Lee County. Drilling was stopped when gas was found at 1,100 feet. It is thought that oil might be found if the well were deepened to 1,400 feet.

Washington.—The Northwestern Natural Gas Co., which formerly distributed natural gas to towns in the Yakima Valley region, has reported that the gas wells in the Rattlesnake Hills field (from which its supply was obtained) were completely depleted in 1941, and the company has changed to butane-air gas for distribution to its customers.

West Virginia.—Information on natural-gas developments in West Virginia has been supplied by David B. Reger, consulting geologist, Morgantown, W. Va.

Various wildcats extended the proved area of existing gas pools in West Virginia in 1942 but opened no strictly new ones. Out of 53 wildcats drilled, 27 were completed as gas wells and 6 as oil wells. About 51,000 additional acres were proved for gas in old fields, and the opening of new pools by wells previously drilled was confirmed. It is probable that the new proved gas reserves represent a substantial increase over withdrawals.

The State had 536 gas completions during 1942, with a total daily open flow of 1,228,501,000 cubic feet compared with 558 wells reported drilled in 1941 with a total daily open flow of 949 million cubic feet. These figures indicate a 4-percent decline in number of wells drilled in 1942 but a 29-percent increase in total daily capacity. During the year, 76 old wells were deepened, adding 26,034,000 cubic feet to production, compared with 86 wells and 56 million cubic feet in 1941.

Drilling increased in the deep Oriskany sand in 1942, and 205 out of 242 tests were successful. This compares with 166 commercial completions in 1941. The Oriskany sand furnished 86 percent of the initial production during the year compared with 75 percent in 1941. Most of the Oriskany gas comes from the Charleston field in Jackson, Kanawha, and Putnam Counties. Only 2 of the 15 tests drilled in other areas found Oriskany gas in commercial quantities, and they were small. The Charleston field is well defined to the north and east by a number of dry holes. It might be extended to the south as far as northern Boone County, where 6 small Oriskany wells have been drilled. Ten or twelve wells showing tight or thinned-out sands indicate a limit to its extent to the west. It is estimated that nearly one-half of the available gas has been recovered from the proved area. About 120 billion cubic feet were withdrawn in 1942.

The Trace Fork field in Putnam County was the most active of the shallow fields, with 40 completions in the Big Lime, Berea, and Brown Shale sands. The Spurlockville field in Lincoln County and the Villa Nova in Braxton and Clay Counties were next in rank, with 17 completions each.

The counties of greatest activity and the number of gas completions in each were: Jackson, 150; Kanawha, 59; Putnam, 48; Upshur, 33; Boone, 30; Calhoun, 29; Clay, 28; Gilmer, 26; and Ritchie, 18.

Production was raised in Kanawha and Raleigh Counties and other areas by acidizing lime wells. The practice of storing gas in depleted sands to build up a reserve to meet peak demands is gaining in importance. One company reported six such projects in use in Pennsylvania and West Virginia in 1942 and two others under test.

Marketed production in West Virginia is estimated at 220 million cubic feet in 1942—a 6-percent gain over the 208 million reported in 1941.

Wyoming.—Three gas wells were drilled in old fields in Wyoming during 1942, one each in the Big Sand Draw, North Baxter Basin, and Pilot Butte fields. The total daily initial flow was 38 million cubic feet, compared with 56 million from five wells drilled in the old fields in 1941. The Pilot Butte field has no pipe-line connections, and the gas is used for field operations only.

Digitized by Google

Three gas wells, with a total initial flow of 14 million cubic feet, were drilled in the new Sherard field. The field was connected with the gas system from the Lost Soldier area to Sinclair, Wyo., by 9 miles of welded line.

L. G. Snow, assistant supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo., reports production from 43 fields in Wyoming in 1942. Big Medicine Bow continued the decline that began several years ago. Salt Creek had 583 million production less than in 1941. Muskrat and several small fields declined, but in general the trend was upward.

Gross production amounted to 46,471 million cubic feet—a 7-percent gain over the 43,409 million produced in 1941. The most productive areas and quantities produced were: Salt Creek, 8,926 million cubic feet; Lance Creek, 7,917; South Baxter Basin, 5,784; Big Sand Draw, 5,652; Elk Basin, 2,241; and Garland, 2,101.

Only 716 million cubic feet of gas were lost in 1942, 1,404 million were used in the field, and 14,322 million were returned to formations, leaving 30,029 million to be marketed. Gas marketed was 6 percent more than the 28,317 million marketed in 1941 and 13 percent over the 1940 record. South Baxter Basin, with 5,774 million, and Big Sand Draw, with 5,652 million, led in volume of gas marketed, supplying over one-third of the total amount. Salt Creek, which ranked first in gross production, stood third in amount of gas marketed, with 2,744 million, and Lance Creek, second in gross production, ranked fourth with 2,141 million.

Repressuring was practiced in eight fields during the year. In Salt Creek 6,182, in Lance Creek 5,775, and in Wertz 1,172 million cubic feet of gas were returned to the sands. Comparatively small amounts were also injected in Rock Creek, Lost Soldier, Elk Basin, La Barge, and Grass Creek fields, bringing the total to 14,322 million—a gain of almost 15 percent over the 1941 figure.

Salt Creek with 8,926, Lance Creek with 7,856, and Big Sand Draw with 5,652 million supplied 96 percent of the 23,254 million cubic feet of gas treated for natural gasoline. Rock Creek, Elk Basin, and Grass Creek supplied the other 4 percent. In 1941, 22,366 million feet were treated.

CONSUMPTION

Consumption of natural gas in 1941 continued the upward trend evidenced since 1938, totaling 2,805,192 million cubic feet. This was a 6-percent gain over the peak of 2,654,659 million cubic feet attained in 1940. Increases over 1940 were made in all but five States. Domestic consumption declined 0.4 percent from 1940, although the number of consumers increased. The over-all gain was in the industrial load, as shown by an 18-percent increase in gas used by miscellaneous industrial consumers in 1941, largely owing to rapidly increasing demands from defense industries. The average value of total consumption increased 0.4 cent over the 1940 average to 22.1 cents a thousand cubic feet.

Ohio produced only 31 percent of the State requirements and ranked first in imports from other States. Texas again ranked first in amount consumed, followed by California, Louisiana, Oklahoma, Pennsylvania, and Ohio in the order named.

Ohio	33,625	28,488	32,703	38,547	37,546
Oklahoma	338,007	265,746	219,755	219,255	200,319
Pennsylvania	31,508	22,600	26,662	40,161	43,704
Texas	754,696	752,784	914,701	1,123,236	1,325,471
West Virginia	140,512	122,301	140,982	168,206	195,093
Wyoming	18,684	17,000	16,483	19,092	21,568
	2,108,800	2,035,562	2,150,000	2,471,400	2,763,300
Ratio to total consumption	88	89	87	93	99

Treated for natural gasoline.—The amount of natural gas processed for natural gasoline increased 12 percent, or from 2,471,400 million cubic feet in 1940 to 2,763,300 million in 1941. The ratio to total consumption was 99 in 1941 compared with 93 in 1940. Gas treated in Louisiana increased 32 percent and in Texas 18 percent over the 1940 volumes, largely because of increases in cycle-plant operations. The amount in Kansas increased 17 percent and in West Virginia 16 percent. In Oklahoma it decreased 9 percent and in California 1 percent.

Domestic and commercial.—Domestic consumers used 442,067 million cubic feet of natural gas in 1941, compared with 443,646 million in 1940. The number of consumers increased by 484,880 and totaled 9,730,110 in 1941. The decrease in consumption in the face of added meters is partly explained by higher average temperatures in 1941 over 1940 and may also represent a more frugal use of fuel following rising living costs. The average consumption per domestic consumer was 45,433 cubic feet in 1941 compared with 47,986 cubic feet in 1940. Commercial consumption increased 8 percent over 1940 to 144,844 million cubic feet.

The average value of domestic gas was 72.0 cents a thousand cubic feet in 1941 compared with 71.1 cents in 1940; the average of commercial gas was 47.2 compared with 47.8.

Field.—Gas used in the field totaled 686,158 million cubic feet in 1941 compared with 711,861 million in 1940. The apparent decline resulted from the use of a new basis of reporting by a company that has been the largest consumer in Texas. The amount actually consumed in the field in 1941 probably increased several percent over the 1940 total. The estimated value of gas used for field purposes was $29,993,000 compared with $27,158,000 in 1940. These figures indicate a gain of 0.6 cent a thousand cubic feet in 1941.

Carbon-black manufacture.—An increase in the proportion of high-yield carbon blacks manufactured, together with a 3-percent decline in total output, reduced the amount of gas used at carbon-black plants in 1941. The total declined 1 percent to 365,377 million cubic feet from 368,802 million in 1940. A gain of 0.1 cent was recorded in the average value, mainly because of a higher average in Texas. The total value was $4,135,000 in 1941 compared with $3,702,000 in 1940.

Petroleum refineries.—Petroleum refineries consumed 148,127 million cubic feet of natural gas in 1941—a 16-percent gain over the 128,007 million used in 1940. This was 18 percent of the total B. t. u. requirements of the industry in 1941—0.9 percent more than was supplied in 1940. As similar comparisons for fuel oil show a loss of 1.6 percent, it would appear that natural gas was used as a substitute for that fuel at some refineries in 1941.

Electric public-utility power plants.—Requirements from public-utility power plants totaled 205,156 million cubic feet in 1941, a 12-percent gain over 1940. Of the major consuming States, sharp gains were noted in Louisiana, Texas, and Kansas, where gas was cheap. California used 13 percent less gas for this purpose in 1941 than in 1940, probably because of the increased use of water power. Tennessee and Arkansas reported sharp increases and Illinois a sharp decrease.

Portland-cement plants.—Consumption at portland-cement plants increased 29 percent to 54,208 million cubic feet in 1941 compared with 41,949 million in 1940. A very small percentage of the total fuel requirements of the industry is furnished by natural gas. However, as its proportion of the total increased slightly in 1941 and that of fuel oil decreased, it may be supposed that gas has displaced oil in some cases.

Other industrial.—Natural gas used for "other" industrial purposes increased 25 percent between 1939 and 1941. It totaled 759,255 million cubic feet in 1941, 18 percent over the 642,594 million used in 1940. Gas used by this class of consumers was 27 percent of the total consumption in 1941 compared with 24 percent in 1940 and displaced field use for the first time in volume. Field use took 24 percent of the total consumption in 1941 compared with 27 percent in 1940.

Miscellaneous industrial consumption increased in all States but New York, Oklahoma, and South Dakota. California, the largest consumer in both years, gained 15 percent over 1940; Pennsylvania, second in rank, gained 33; and Louisiana, third, gained 10. These three States consumed one-third of the total gas used for miscellaneous industrial purposes in 1941.

[1] Gas used in portland-cement plants included under "Miscellaneous" for United States total and under "Other industrial" for State total to avoid disclosing figures of individual operators.

[2] Maryland includes District of Columbia and Virginia.

[3] Gas used in carbon-black manufacture included under "Miscellaneous" for United States total and under "Other industrial" for State total to avoid disclosing figures of individual operators.

[4] Utah includes North Dakota.

Digitized by Google

The average value of the gas consumed at petroleum refineries, electric public-utility power plants, and portland-cement plants, and for "Other" industrial purposes was 17.1 cents in 1941 compared with 16.7 cents in 1940. This 0.4-cent gain may be attributed to large gains in volume in some of the Eastern States, where high prices prevail.

Mixed gas.—The use of natural gas mixed with manufactured gas increased 1 percent in 1941 over 1940. The total volumes were 65,979 million cubic feet in 1941 and 65,102 million in 1940. Illinois, which has been the largest consumer of mixed gas, and New York, next in rank, both decreased about 1 percent in the quantity of natural gas blended. The number of consumers increased in most States. The total number of domestic and commercial consumers was 2,619,100 in 1941 compared with 2,514,910 in 1940. Natural gas used in mixed gas was valued at $56,952,000 compared with $56,202,000 in 1940. The average value remained unchanged at 86.3 cents per 1,000 cubic feet.

Consumption of natural gas used with manufactured gas in the United States in 1941, by States

INTERSTATE SHIPMENTS

Interstate shipments totaled 815,672 million cubic feet in 1941—a 10-percent increase over 1940. Gas was transported from 21 States in 1941.

New shipments were reported from Arkansas to Louisiana and Texas. Some Texas gas was turned into the pipe line serving Alabama, Georgia, and Mississippi. The States that transported the largest volumes of interstate gas in 1941 were Texas, Louisiana, and West Virginia in the order named. Sharp decreases were noted in New York and Mississippi. Industries in Pennsylvania that formerly drew their natural-gas supplies from New York are now using West Virginia and Kentucky gas. Texas supplied 32 percent of the total shipments in 1941, Louisiana 24, and West Virginia 17, the same proportions as in 1940. Shipments from Pennsylvania to New York continued the recession started in 1940.

PIPE-LINE DEVELOPMENTS

Because of the steel shortage, the construction of gas lines came under strict supervision of the War Production Board. The relatively more urgent need for pipe-line expansion in crude oil led to the conversion of some gas-line mileage to oil lines as part of the several projects supervised by the Petroleum Administration for War. The net gain in gas-line mileage was therefore small—possibly smaller than for any year since before the boom period, 1928–30.

Permission was granted to remove pipe from the Rodessa loop. After reconditioning, part of the line was to be relaid to meet the increased demand in the Dallas-Fort Worth area. In February a 139-mile line was started from the South Arkansas gas fields near Columbia to supply gas to two plants. The gas is sour, and desulfurization plants were built to make it marketable. The fields in Southern Arkansas were also the starting point for an 18-inch line to Little Rock and other communities in the central part of the State.

The Federal Power Commission granted permission for the Border Pipe Line Co. to build a line from the San Salvador fields in Hidalgo County, Tex. Plans for a 772-mile line from the Louisiana and Texas gas fields to Ohio, Pennsylvania, and West Virginia were considered but were still under advisement at the end of the year. The Lone Star Gas Co. started a line from Groesbeck to connect with the 18-inch main line at Buffalo. The Natural Gas Pipe Line Co. of America duplicated its 800-mile line of 24-inch pipe with 26-inch pipe to transport more gas from the Panhandle. A 12-inch line was laid from the Chickasha and Cement gas fields in Oklahoma to an Army cantonment. A 12-inch line between Manchester and Kalamazoo, Mich., was started in September 1942. A permit was granted for a 275-mile trunk line from Ohio to Kalamazoo. The line from the Lirrette gas field in Louisiana to Mobile was put in operation in February 1942 to supplement the line from Jackson.

NATURAL GASOLINE

SUMMARY

The natural-gasoline industry experienced a satisfactory year in 1942 in point of volume. The total output of all the light products—natural gasoline, cycle products, and liquefied petroleum gas—reached the record-breaking total of 3,509,814,000 gallons or 3 percent above 1941. However, this showing was due mainly to expanded cycle operations, as the output of natural gasoline alone was 8 percent below 1941.

Prices of natural gasoline were favored by starting the year well above the corresponding levels of 1941, but owing to price ceilings and transportation difficulties the trend in 1942 was generally downward. The average price for 26–70 grade in 1942 was 3.22 cents per gallon compared with 3.70 cents in 1941.

As with production, the trend in stocks in 1942 depends on the products that are considered. Including liquefied petroleum gas, the trend was upward, but for natural gasoline and cycle products there was a decline. In any event, the pronounced draft on stocks that characterized 1941 was not repeated, which was probably another reason for the price weakening.

Participation in the war program was a primary consideration of the industry in 1942. This participation took many forms, depending on products made, size, and location. Probably the most important roles were as suppliers of materials for aviation gasoline and rubber. Of these, aviation gasoline was by far the larger in volume. The liquefied-gas branch of the industry performed admirably in supplying fractions, mainly isobutane and isopentane, for aviation-gasoline manufacture, in addition to assuming added responsibilities for supplying certain war plants with fuels.

[1] Data for 1942 are preliminary; detailed statistics with final revisions will be released later.
[2] Tables compiled by E. M. Seeley, Petroleum Economics Division, Bureau of Mines.

Digitized by Google

The shortage of materials prevented much expansion in capacity. Losses in manpower were serious but not crippling. Ordinary research slowed, but much was learned as to the use of the light fractions in aviation gasoline and various chemicals, which should reduce the dependence of the industry on ordinary refinery blending in the postwar period.

PRICES AND MARKET CONDITIONS

Although most spot prices for natural gasoline opened 1942 well above those for 1941, the decline beginning in February and reaching its lowest level in March brought prices below the 1941 average. The result was that the average for the 26–70 grade in Oklahoma, used as the market indicator, declined from 3.70 cents per gallon in 1941 to 3.22 cents in 1942. However, as the fluctuation in spot prices invariably is more pronounced than changes in the national average, the decline for the national average is estimated at 3.9 cents per gallon in 1941 to 3.8 cents in 1942. As indicated in figure 1, the downward movement in natural gasoline was contrary to the trend in the representative refinery-gasoline price (Oklahoma) used.

Digitized by Google

However, the divergence in the trends was not enough to justify the feeling that the general relationship between these two prices has been greatly disturbed. The increase in natural-gasoline stocks at plants (see fig. 1) may have had something to do with the lower quotations; likewise, the decline in finished gasoline stocks may have influenced prices upward in spite of price ceilings.

PRODUCTION

Trends in total output.—The output of natural gasoline and cycle products trended upward in 1942, but crude-oil production decreased (see fig. 2). In relative terms, the gain in natural gasoline and cycle products was 1 percent and the loss in crude oil 1 percent. However, when cycle production, which has no direct relationship to crude-oil operations, is eliminated the curve for natural gasoline alone declines 8 percent. Part of the reason for this large decrease is that an increasing amount of lighter fractions of natural gasoline is being produced as liquefied petroleum gas.

The trend of the total output of light products (natural gasoline, cycle products, and liquefied gas) in 1942 was similar to crude oil in that both were downward from January to April but upward for the next 4 months. From then on the output of light products was upward, but the course for crude oil flattened.

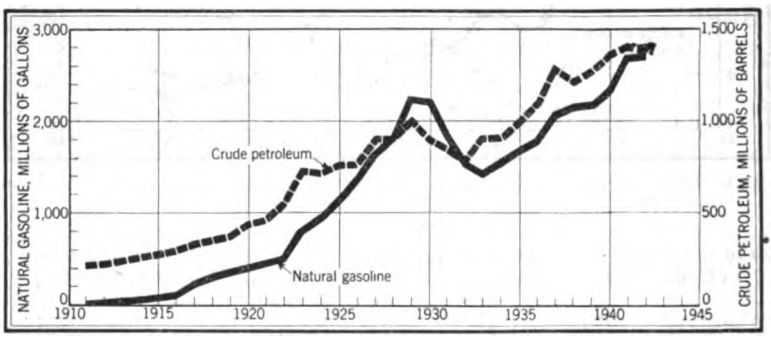

FIGURE 2.—Annual production of natural gasoline and crude petroleum, 1911–42.

Natural gasoline and cycle products produced in the United States, 1938–42, by States, in thousands of gallons

California.—Natural-gasoline production continued to decline in California, as the total of 545,437,000 gallons was 5 percent below 1941. As in 1941, the decline was due to a further drop in the Kettleman Hills field. Output in the old Los Angeles Basin fields continued to hold up exceptionally well, and some of them—like Huntington Beach—made gains.

Monthly production of natural gasoline and allied products in the United States, 1941–42, by fields, in millions of gallons

The output of liquefied petroleum gases at natural-gasoline plants in California rose from 82,638,000 gallons in 1941 to 89,973,000 gallons in 1942, a modest gain for this branch of the industry.

Louisiana.—The production of the three light products in Louisiana increased 33 percent in 1942 over 1941. This increase was confined to cycle products (up 87 percent) and liquefied petroleum gases (up 110 percent), as the output of natural gasoline declined 22 percent. Much of the gain was due to the full year's operation of the large cycle plant in the Cotton Valley field.

Oklahoma.—Production in Oklahoma followed the usual trend, that is, with natural gasoline decreasing and liquefied petroleum gases increasing. In this case, however, the gain in gases was less than the loss in natural gasoline; hence the total declined 2 percent. There are no real cycle plants in the State.

Texas.—Production in Texas followed the same trend as in Louisiana, with increases for cycle products, liquefied petroleum gases, and the total but with a decline for natural gasoline. The total set a new record of 1,586,772,000 gallons, or 2 percent more than in 1941. The output of cycle products increased 28 percent and liquefied petroleum gases 5 percent, but natural gasoline declined 13 percent.

Natural gasoline and allied products produced and natural gas treated in the United States in 1941, by States [1]

The record of production by the major districts in Texas in 1942 shows the Gulf rapidly forging to the front but East Texas and the Panhandle losing ground, primarily because no cycle plants and little additional fractionating equipment were built outside of the Gulf district and adjoining counties in 1941 and 1942. As a matter of fact, the East Texas field did an outstanding job in holding its 1942 decline to less than 1 percent.

Other States.—Although the majority of this group declined in output in 1942, the total for all increased 9 percent, or from 498,219,000 gallons in 1941 to 541,485,000 gallons in 1942. This gain roughly equaled the rise in output of Illinois, where increased production, particularly of liquefied petroleum gases, continues to expand even though the gross gas output is declining. New Mexico and West Virginia continued to gain, but Kansas showed an unexpected decline.

CONSUMPTION AND MOVEMENTS

The total demand for all light products except liquefied refinery gases increased from 3,455,928,000 gallons in 1941 to 3,501,624,000 gallons in 1942—a rise of 1 to 2 percent. The gain was divided between cycle products and liquefied petroleum gases, as natural gasoline alone declined about 10 percent.

The figures in the distribution table of this chapter indicate a material increase in the refinery utilization of natural gasoline and allied products in 1942; actually, however, there may have been a decline, because the production figures for 1941 were revised upward to include 707,196,000 gallons of liquefied petroleum gas, but the totals for refinery utilization were left unchanged. This threw most of the liquefied petroleum gases in 1941 into "sales to jobbers and retailers." This item consequently declined radically in 1942, when most of the gas was included in the proper category, "used at refineries."

Losses and exports rose from 345,618,000 gallons in 1941 to 392,616,000 gallons in 1942. Although these two figures are not exactly comparable, probably there was an actual increase in this item.

Percentage of natural gasoline and allied products in refinery gasoline in the United States, 1938–42, by districts

Year	East Coast	Appalachian	Indiana, Illinois, Kentucky	Oklahoma, Kansas, Missouri	Texas Inland	Texas Gulf Coast	Louisiana Gulf Coast	Arkansas and Louisiana Inland	Rocky Mountain	California	Total
1938	1.6	1.4	4.7	8.8	15.5	4.3	2.2	6.8	5.8	17.6	7.2

Refinery utilization.—The proportion of natural gasoline used at refineries increased from 7.1 percent in 1941 to 9.7 percent in 1942, but here also is a lack of comparability. The figures for most of the districts are comparable; for example, the decline indicated for the East coast and the gain in California undoubtedly occurred.

Direct sales.—Comparable data on "direct sales," or sales to other than refiners, are lacking in 1942. This type of distribution would be expected to increase, as much of the cycle production never reaches a refinery.

STOCKS

Stocks of natural-gasoline and cycle products continued to decline in 1942, although the net change was much less than in 1941. The total, as of December 31, 1942, was 170,898,000 gallons compared with 179,550,000 gallons the first of the year. The decrease of about 9,000,000 gallons comprised a decline of about 14,000,000 gallons in natural gasoline and an increase of about 5,000,000 gallons in cycle products. Stocks of liquefied petroleum gases nearly quadrupled during the year; stocks of liquefied refining gases at refineries increased. Including the two kinds of liquefied gases (petroleum and refinery), stocks increased from 191,730,000 gallons on January 1 to 203,490,000 gallons on December 31.

The downward trend in natural-gasoline stocks in California in 1941 carried over into 1942. As the decline in California exceeded the national total, stocks of natural gasoline east of California increased. Quantitatively most of the increase east of California was at plants in Texas, although several other States had larger relative gains.

Stocks of natural gasoline and allied products in the United States in 1942, by months, in thousands of gallons

TECHNOLOGIC DEVELOPMENTS

Cycling plants.—The equipment shortage brought on by the war prevented much expansion of the cycling branch of the industry, but some plants on which construction was started in 1941 were completed and put in operation in 1942. Thus 37 plants were reported as operating in 1942 compared with 30 in 1941 and 24 in 1940. These figures include only bonafide cycling plants and not natural-gasoline plants that repressure.

Cycling plants in Texas processed 425,000,000,000 cubic feet of gas in 1942 and obtained an average yield of 0.92 gallon of liquid per

Digitized by Google

thousand cubic feet. The plants in Louisiana processed about 42,000,000,000 cubic feet, with a considerably higher yield.

Yields.—The average yield for natural gasoline and cycle products in 1941 was 0.97 gallon per thousand—a slight increase over the 0.95 gallon for 1940. This gain may be attributed principally to an increase in Texas from 0.83 gallon in 1940 to 0.89 gallon in 1941 and in Illinois from 1.69 to 2.31. The gain in yields in Illinois in 1940 and 1941 is typical of the performance of a group of fields that have experienced too rapid withdrawal of crude oil. In nearly all such fields the output of casinghead gas declines rapidly, but its gasoline content increases.

Natural gasoline and allied products produced in the United States in 1941, by States and by methods of manufacture [1]

[1] Figures for 1942 not yet available.
[2] Includes 22 plants manufacturing liquefied petroleum gases.
[3] Includes combination of absorption process with compression and charcoal processes.
[4] Includes 159 plants manufacturing liquefied petroleum gases.
[5] Includes 8 plants manufacturing liquefied petroleum gases.
[6] Drip gasoline.
[7] Does not include liquefied petroleum gases.

Production by processes.—In previous years cycle plants were classed as compression plants; in consequence, that group increased in relative importance during 1939 and 1940. However, in this year's table on "methods of manufacture" the number of cycle plants and the production are shown separately, by States. The data for 1941 (1942 figures for other than cycle plants are not yet available) indicate that the three old classes (compression, absorption, and charcoal) all declined in number of plants compared with 1940. Compression production probably declined throughout 1942, absorption production probably declined in 1942 after a gain in 1941, and the small output of charcoal plants probably declined in 1942.

Trends in vapor pressures.—During the year the Bureau's monthly questionnaire on natural gasoline was revised, and the queries on vapor pressure of shipments were replaced by items covering a breakdown of production by vapor pressures. Data on the new basis for

Digitized by Google

east of California for 1942 show an average vapor pressure of 20.5 pounds. This compares with an average of 19.7 pounds for total shipments east of California in 1941.

Technical trends.—Because of the shortage of materials, little in the way of new equipment and methods was introduced in the natural-gasoline industry in 1942. The primary consideration continued to be the maximum use of isobutane, isopentane, and other fractions in the aviation-gasoline program. It has been reported that participation of the industry in aviation-gasoline production will approach 70,000 barrels daily by the end of 1943. The extent to which the rubber and other war programs depend on natural gasoline and allied products for raw materials is probably increasing, but relatively the quantities involved are small.

LIQUEFIED PETROLEUM GASES

Sales of liquefied petroleum gases continued to expand strongly in 1942, as in recent years; however, difficulties connected with the war probably prevented full supplying of the potential market. Distributors of liquefied petroleum gases reported sales of 585,440,000 gallons in 1942—a 27-percent gain over 1941 deliveries of 462,852,000 gallons. The increase in 1942 compares with a 48-percent growth in demand in 1941 and a 40-percent gain in 1940, and it is surprising that dealers troubled by the shifting of supplies to raw material uses, inadequate transportation, lack of sufficient equipment, and other handicaps made the showing reported. The fact that the general public is rapidly learning to appreciate the many advantages and diversified uses of liquefied petroleum gases is evident in the rapidly growing market demand, which has approximately doubled since 1940.

Sales of liquefied petroleum gases in the United States, 1936–42, in thousands of gallons

Year	Butane	Propane	Butane-propane mixtures	Pentane	Total	
					Quantity	Percent of increase over preceding year
1936	40,200	36,502	27,375	2,575	106,652	38.8
1937	45,399	46,474	46,694	2,833	141,400	32.6
1938	52,768	54,130	56,050	2,253	165,201	16.8
1939	71,351	79,323	69,020	3,886	223,580	35.3

1941	112,244	126,969	219,252	4,387	462,852	47.7
1942 [1]	128,560	150,511	301,917	4,452	585,440	26.5

[1] Subject to revision.

All principal uses of liquefied petroleum gases made important gains in 1942 over 1941. The quantity (299,559,000 gallons) reported for domestic or household consumption in 1942 was 36 percent above the 1941 total (220,722,000 gallons)—a percentage increase somewhat below those made in 1941 (65 percent) and 1940 (53 percent); however, it must be realized that normal distribution to increasing numbers of consumers was impossible under conditions prevailing in 1942. Gas-manufacturing companies purchased 24 percent more liquefied petroleum gases in 1942 (31,366,000 gallons) than in 1941 (25,255,000 gal-

Digitized by Google

lons), about the same gain in requirements as was made in 1941 over 1940. A 41-percent expansion in the sales of liquefied petroleum gases for industrial fuel reported in 1941 (98,728,000 gallons) was not reached in 1942 (114,132,000 gallons), as the increase over 1941 was only 16 percent. Difficulty in obtaining the more desirable butane for use as an industrial fuel was probably one of the reasons for the smaller relative growth in this particular use in 1942. Manufacturers of chemicals required 53,038,000 gallons of liquefied petroleum gases in 1942 or 20 percent more than the 1941 total of 44,206,000 gallons—a gain compared with a 28-percent increase in 1941 over 1940. Deliveries of 82,456,000 gallons of liquefied petroleum gases for internal-combustion-engine fuel in 1942 were 23 percent above the 1941 total of 66,871,000 gallons or about the same increment (24 percent) as reported in 1941.

About one-fifth (22 percent) of total liquefied petroleum gas sales in 1942 was reported as butane compared with one-fourth (24 percent) in 1941 deliveries. This drop in the butane proportion in the 1942 total followed a downward trend of recent years and a change that probably will continue as more butane is diverted for the manufacture of motor fuel, rubber, and other products. The propane share in the marketed production of liquefied petroleum gases also continued to decrease (27 percent in 1941 and 26 percent in 1942), while the proportion of butane-propane mixtures in total deliveries accounted for a larger percentage. Butane-propane mixtures replacing butane for many uses constituted about 52 percent of total sales of liquified petroleum gases in 1942 compared with a 47-percent share in 1941. Pentane, which is relatively unimportant in volume, made up less than 1 percent of total requirements both in 1941 and 1942.

Sales of butane increased from 112,244,000 gallons in 1941 to 128,560,000 gallons in 1942—a 15-percent gain. The rate of increase in 1942 was well below the 46-percent expansion for butane deliveries in 1941. The gains for the principal uses of butane were smaller than those reported for 1941, except for the chemical-manufacturing industry, which purchased 5,256,000 gallons of butane in 1942 compared with negligible amounts in previous years. Butane as well as propane is evidently replacing butane-propane mixtures as raw material at chemical plants, as "mixtures" showed a small decline in 1942: Butane delivered for internal-combustion-engine fuel, which increased 67 percent in 1941 over 1940, dropped from 18,799,000 gallons in 1941 to 14,870,000 in 1942, a loss of 21 percent, evidently because of the diversion of butane to war industries.

The marketed production of propane was reported as 150,511,000 gallons in 1942 compared with 126,969,000 gallons in 1941, an increase of 19 percent and a rate slightly above the 16-percent gain realized in 1941. The quantity of propane delivered for domestic use—113,249,000 gallons in 1942—was 16 percent (42-percent gain in 1941 over 1940) above the 1941 total of 98,048,000 gallons. The much lower rate of expansion in 1942 reflects the inability of distributors to fully supply the potential domestic market under disturbed conditions prevailing during the year. Gas-manufacturing companies bought 26 percent less propane (4,957,000 gallons in 1942 and 6,678,000 in 1941) in 1942 but increased their purchases of butane (by 2 percent over 1941) and butane-propane mixtures (119 percent over 1941).

Digitized by Google

Propane delivered to manufacturing plants rose by 23 percent, from 16,730,000 gallons in 1941 to 20,601,000 in 1942. Industrialists turned to propane for fuel and other uses in 1942 as more of the butane supply was diverted to other channels. This is a change from 1941, when less propane (by 50 percent) was used by manufacturers than in 1940. The requirements for propane by chemical plants increased from 1,528,000 gallons in 1941 to 5,850,000 in 1942, paralleling a similar gain in butane sales to manufacturing chemical firms. The quantity of propane reported as internal-combustion-engine fuel nearly doubled in 1942 (3,112,000 gallons in 1942 compared with 1,631,000 in 1941), replacing butane used as motor fuel, which showed a drop in 1942.

The marketed production of butane-propane mixtures rose from 219,252,000 gallons in 1941 to 301,917,000 gallons in 1942. The 38-percent gain for 1942 was far below the 78 percent expansion in deliveries reported for 1941; however, the percentage increase for butane-propane mixtures in 1942 was still well above the rates reported for the other liquefied gases, as it was in 1941. All principal demands for butane-propane mixtures showed substantial gains in 1942 over 1941, except for a minor decline (2 percent below 1941) in the quantity credited to chemical manufacturers. The domestic use of butane-propane mixtures increased from 87,673,000 gallons in 1941 to 140,516,000 in 1942 or by 60 percent compared with over a 100-percent gain in 1941. Incidentally, the quantity of butane-propane mixtures reported for domestic use in 1942 exceeded for the first time the propane delivered for the same purpose. Sales of butane-propane mixtures to gas-manufacturing companies more than doubled in 1942 (13,961,000 gallons in 1942 compared with 6,368,000 in 1941) contrasted with a minor increase (2 percent over 1941) in butane requirements and a sharp decline (26 percent below 1941) in purchases of propane. The quantity of butane-propane mixtures used as industrial fuel in 1942—43,011,000 gallons—was 22 percent above the 1941 total—35,287,000 gallons. Butane-propane mixtures are important as raw material for the manufacture of chemicals; however, requirements dropped slightly from 39,243,000 gallons in 1941 to 38,325,000 in 1942, in contrast with larger purchases of butane and propane by chemical plants. The demand for butane-propane mixtures for motor fuel—64,470,000 gallons in 1942—was 39 percent above 1941 requirements—46,441,000 gallons. The indications are that butane (21-percent decrease in 1942) for this purpose is being replaced mostly by butane-propane mixtures and less extensively by propane.

Deliveries of pentane increased slightly from 4,387,000 gallons in 1941 to 4,452,000 in 1942. The larger share of this gas is used in the manufacture of chemicals, the quantity increasing from 3,146,000 gallons in 1941 to 3,607,000 in 1942. The sales of pentane for domestic consumption, which rose from 656,000 gallons in 1940 to 1,128,000 in 1941, declined to 766,000 in 1942.

The changing proportions of the various liquefied gases sold to satisfy the principal uses are of special interest. Butane delivered for domestic consumption has remained at about 15 percent of total requirements in recent years, whereas the proportion of propane so used has declined from about 51 percent in 1940 to 38 percent in 1942, and the butane-propane mixtures have gained in about the reversed ratio. Liquefied petroleum gases sold to gas-manufacturing companies in

Digitized by Google

1940 were over half butane and about a quarter propane; but in 1942 butane-propane mixtures represented the larger share (45 percent), with corresponding losses in the butane and propane percentage totals.

[1] Revised figures.
[2] Subject to revision.

Industrial fuel was approximately 48 percent butane in 1940 and 1941, but the proportion dropped to 44 percent in 1942, as butane was diverted for raw material. Propane, which comprised 47 percent of the industrial fuel total in 1940, dropped to 17 percent in 1941 and 18 percent in 1942. Butane-propane mixtures rose from 5 percent of the industrial fuel total in 1940 to 36 percent in 1941 and 38 percent in 1942. "Mixtures" used for raw materials in the manufacture of chemicals constituting about 88 percent of the total demand in 1940 and 1941 declined to 72 percent in 1942, and the butane and propane proportions each rose to about 10 percent of the total. Pentane delivered to chemical manufacturers has declined from 9 percent of

Digitized by Google

total requirements in 1940 to 7 percent in 1942. Butane used for motor fuel increased from 21 percent of the total in 1940 to 28 percent in 1941 but then declined to 18 percent in 1942. Butane-propane mixtures made up 70 percent of the internal-combustion-engine fuel total in 1941 and 78 percent in 1942.

The American Gas Association has furnished the following data concerning the distribution of liquefied petroleum gas by manufactured-gas companies in 1942:

At the end of 1942, liquefied petroleum gas was being delivered through mains to consumers in 208 communities in 31 States by 92 companies supplying 69,140 consumers.

Butane-air gas with heating value ranging from 520 to 1,300 B. t. u. per cu. ft. was supplied to 153 communities in 30 States. A mixture of undiluted butane and propane gas with a heating value of 2,800 to 3,000 B. t. u. per cu. ft. was supplied to 15 communities in Arizona, California, and Nevada. Undiluted propane gas with a heating value of 2,550 B. t. u. per cu. ft. was supplied to 40 communities in Maryland, Minnesota, New Jersey, North Dakota, Virginia, and Wisconsin.

Bulk shipments of liquefied petroleum gases increased from 405,898,000 gallons in 1941 to 517,504,000 in 1942, and quantities handled in cylinders were 56,954,000 gallons in 1941 and 67,936,000 in 1942. The trend toward bulk shipments of liquefied petroleum gases, which was rather pronounced in 1941, was also evident in 1942, and over 88 percent of total deliveries were handled in bulk, either in tank cars or trucks. Shortage of material for making containers and the greater ease of handling bulk shipments under present transportation conditions probably will force an even larger proportion of bulk deliveries in the future.

Deliveries of liquefied petroleum gases in the Pacific Coast area (California, Oregon, Washington, Arizona, and Nevada) increased from 102,885,000 gallons in 1941 to 126,905,000 in 1942, a gain of 23 percent. The demand for liquefied petroleum gases on the Pacific coast represented 22 percent of the national total in both 1941 and 1942. The marketed production of liquefied petroleum gases in all other areas expanded by 27 percent—from 359,967,000 gallons in 1941 to 458,535,000 in 1942.

SUMMARY

A number of factors combined to bring about adverse conditions in the carbon-black industry during 1942. Anticipating a rise in price, which occurred in January, consumers replenished their supplies at the end of 1941. Reductions in exports because of the war, as well as in rubber manufacture, contributed to a decrease in demand that was not offset by increased sales for military purposes. Production declined 3 percent from the 1941 total, whereas sales declined 30 percent, resulting in a large accumulation of stocks held by producers at the end of the year. (See fig. 1.)

In spite of the decline in rubber manufacture in 1942, about 89 percent of domestic sales went to the rubber trade. Toward the end of the year demands from the synthetic-rubber industry were taking up part of the slack. All the major classes of consumption decreased

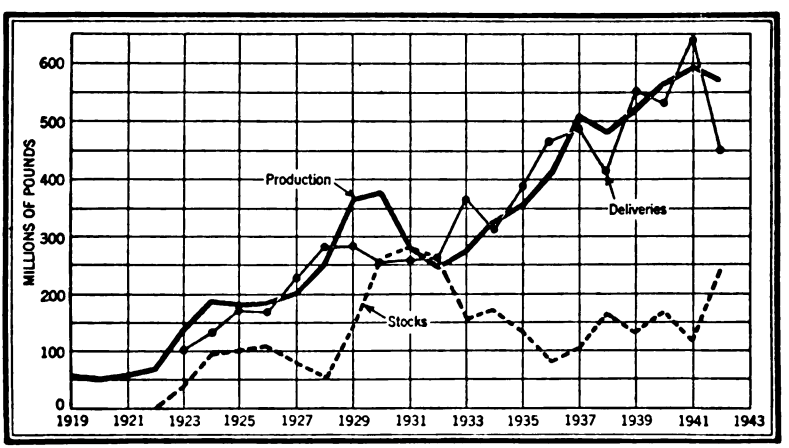

Figure 1.—Production, stocks, and deliveries of carbon black, 1919–42.

Digitized by Google

quantitatively, but their ratio to total demand remained virtually unchanged.

The Office of Price Administration allowed a rise of 0.2 cent a pound for both compressed and uncompressed grades of carbon black the first week in January. Prices were unchanged during the remainder of the year.

1942	574,006	19,547	242,755	334,296	115,635	1.71

[1] Figures not available.
[2] Exports not separately reported by the Department of Commerce before 1925.
[3] For comparison with 1932.

PRODUCTION

By States.—Texas produced 76 percent of the United States total output in 1942 compared with 81 percent in 1941 and 84 percent in 1940. Its output was 434,889,000 pounds, a 9-percent decline from the 1941 record. Although the Panhandle district produced 8 percent less carbon black than in 1941, it contributed 87.5 percent of the State total in 1942 compared with 86.4 percent in 1941.

Louisiana gained 16 percent over 1941, owing principally to increased output of furnace blacks. Production was 90,353,000 pounds in 1942 compared with 78,050,000 pounds in 1941.

Oklahoma and Kansas both had less production than in 1941. New Mexico and California were added to the list of producing States during the year.

Methods and yields.—Because of the growing importance of furnace blacks, it has been decided to divide the figures according to contact processes and furnace or retort processes instead of channel and "Other processes" as has been done in former years.

Louisiana: Monroe-Richland district (Morehouse and Ouachita Parishes)	6	6	90,353,000	3,258,000	3.61	18,040,000	5.01	504,000	2.79
Oklahoma	4	4	24,318,000	809,000	3.33	9,789,000	2.48	163,000	1.67
Texas:									
Panhandle district (Carson, Gray, Hutchinson, Moore, and Wheeler Counties)	16	29	380,536,000	13,152,000	3.46	269,136,000	1.41	3,073,000	1.14
Rest of State (Aransas, Nueces, Stephens, Ward, and Winkler Counties)	5	7	54,353,000	1,816,000	3.34	30,343,000	1.79	230,000	.76
Total Texas	16	36	434,889,000	14,968,000	3.44	299,479,000	1.45	3,303,000	1.10
Total United States	21	50	574,006,000	19,547,000	3.41	335,533,000	1.71	4,338,000	1.29

[1] In counting the total number of producers reporting, a producer operating in more than 1 State, district, or county is counted but once.

Twenty-five percent of the total output in 1942 was produced by furnace processes, 17 in 1941, 13 in 1940, and 11 in 1939. In October 1942 the War Production Board placed furnace blacks under strict allocation control.

Increased production of these high-yield blacks raised the average yield for the United States to a new peak of 1.71 pounds per thousand cubic feet of gas, compared with 1.63 in 1941 and 1.54 in 1940.

Number and capacity of plants.—One plant was shut down in Stephens County, Tex., in 1942, and one new plant was operated in Lea County, N. Mex., and one in Contra Costa County, Calif.—making a total of 50, compared with 49 in 1941.

The total daily capacity of all plants was 1,808,756 pounds compared with 1,716,395 in 1941, a 5-percent gain. It is estimated that plants operated at 87 percent of capacity compared with 95 percent in 1941.

Producers.—The Shell Chemical Co., with a plant in Contra Costa County, Calif., was added to the list of carbon-black producers during the year; otherwise the list remains unchanged from 1941.

[1] Plant, located in both Carson and Hutchinson Counties, counted in Hutchinson County.

DEMAND

Total deliveries.—Carbon-black deliveries reported by producers were 449,931,000 pounds during 1942 compared with 644,744,000 pounds in 1941. There was a sharp decline both in exports and in all major classes of domestic sales. (See fig. 2.)

Domestic consumption.—Domestic deliveries totaled 334,296,000 pounds in 1942 compared with 496,579,000 pounds in 1941, a 33-percent decline. Sales to the major classes of consumers were: Rubber companies, 295,947,000 pounds (88 percent); ink companies, 19,233,000 pounds (6 percent); paint companies, 3,616,000 pounds (1 percent); and miscellaneous, 15,500,000 pounds (5 percent). These quantities are in virtually the same ratio to total sales as in 1941.

Digitized by Google

The curtailment in the rubber industry caused a 33-percent decline in movements to rubber companies. Trade was light up to the middle of the year, when there was a slight improvement. Toward the end of the year deliveries to synthetic rubber manufacturers strengthened the market.

Before the war, when supplies of natural rubber were ample, channel blacks dominated the rubber markets at the expense of furnace blacks. The finer-grained, harder channel blacks were superior in abrasive resistance, which gave them a decided advantage in the manufacture of the average automobile tire, which, in normal times, constitutes the most

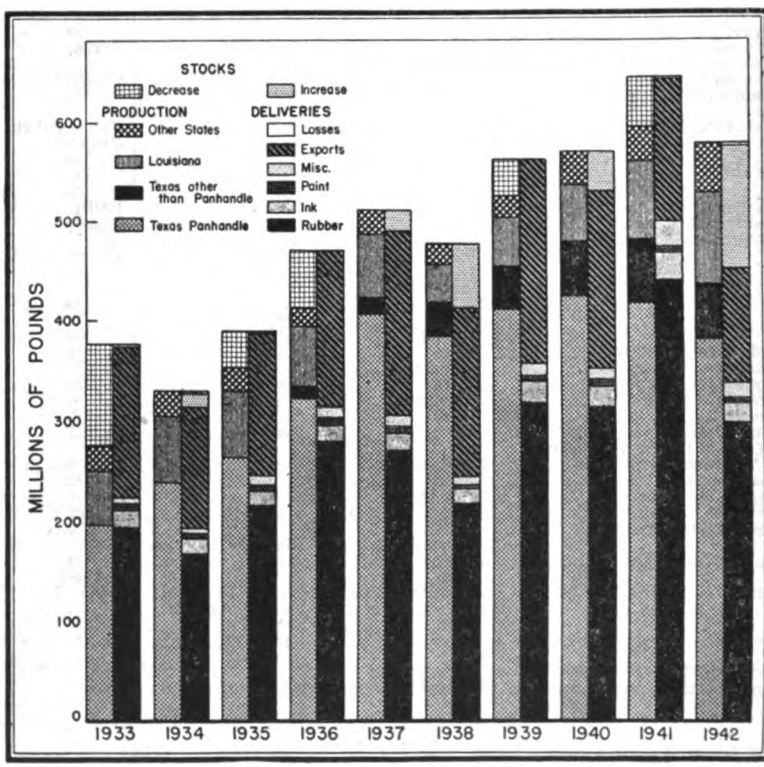

FIGURE 2.—Production and consumption of carbon black, 1933–42. Production in "Texas other than Panhandle" included in "Other States," 1933–35.

important part of the carbon-black market. The only reason furnace blacks survived this competition was their relatively high yield.

When most of the sources of natural rubber were cut off and the synthetic rubber program was projected, the picture changed radically. Most grades of synthetic rubber have higher heat generation and lower tensile strength than natural rubber. Both of these general characteristics call for the use of large amounts of the softer, coarser-grained blacks, which explains why the present trend in construction is toward furnace-type blacks and away from channel blacks.

Digitized by Google

Sales to ink companies amounted to 19,233,000 pounds in 1942 compared with 28,198,000 in 1941. As the quantity of newsprint available for consumption in 1942 was only 3 or 4 percent below 1941, it is apparent from the sales figures that the ink companies did considerable stocking in 1941.

The paint trade was affected by the curtailment in automobile manufacture and the consequent declines in the use of black paints and enamels. Paint companies purchased 3,616,000 pounds of carbon black in 1942, a 38-percent decline from the 1941 figure (5,840,000 pounds).

Deliveries for miscellaneous purposes totaled 15,500,000 pounds in 1942, a 33-percent decline from the 1941 record of 23,039,000 pounds.

Exports and imports.[1]—Exports of carbon black in 1942 continued the decline started in 1940, when the war began to impair foreign trade. A total of 115,635,000 pounds was purchased by foreign countries during the year, a 22-percent decrease from the 148,165,000 pounds purchased in 1941 and a 43-percent decrease from the peak of 203,828,000 pounds recorded in 1939. The total value was $5,229,000 in 1942 and $6,686,000 in 1941, an average of 4.52 and 4.51 cents per pound, respectively. The average for the year 1940 was 4.40 cents.

The United Kingdom continued to be the leading customer, purchasing 58,223,000 pounds (39 percent of the total) in 1941 and 53,297,000 pounds (46 percent of the total) in 1942. Canada ranked second, with 32,760,000 pounds purchased in 1941 and 29,651,000 in 1942.

September was the month of heaviest shipments in 1941 and June in 1942. Galveston, which has been the main shipping point for a number of years, dropped from 115,042,000 pounds exported in 1940 to 61,132,000 in 1941 and to 22,914,000 in 1942. Michigan took first place in 1942 with 29,085,000 pounds shipped out.

Carbon black exported from the United States, 1941–42, by months and customs districts

[1] British India.
[2] United Kingdom of Great Britain and Northern Ireland.

Imports of "gas black and carbon black" rose from 800 pounds valued at $101 in 1941 to 77,870 pounds valued at $7,307 in 1942. Acetylene black imported from Canada declined from 4,063,000 pounds valued at $430,000 in 1941 to 3,840,000 pounds valued at $381,000 in 1942.

STOCKS

Stocks at the end of the year more than doubled the 118,847,000 pounds reported on hand December 31, 1941. A 3-percent decrease in production and a 30-percent decrease in sales caused supplies to accumulate until they totaled 242,755,000 pounds by the end of 1942. This was the highest year-end total since 1932, when 257,998,000 pounds were reported.

PRICES AND VALUES

The average value of carbon black at the plants in 1942 was 3.41 cents, a gain of 0.15 cent over 1941. Prices remained unchanged during the year, except for a small advance during the first week of January. This rise (0.2 cent) brought the quotation for regular, uncompressed black, in bags at the plants, to 3.625 cents a pound.

	Page		Page
Summary	1185	Manufactured or petroleum asphalt	1186
Native asphalts and bitumens	1185	Production	1186
Bituminous rock	1185	Stocks	1187
Gilsonite and wurtzilite	1185	Sales	1187
Sulfonated bitumen	1185	Foreign trade	1190
Exports	1185	Distribution by rail	1190
		Road oil	1192

SUMMARY

Refinery sales of petroleum asphalt (exclusive of road oil) to domestic consumers in the United States were 10 percent larger in tonnage in 1942 than in 1941; and, because of higher prices, they were 17 percent larger in value. As the refinery output was 4 percent less than in 1941 and imports were 22.5 percent lower, inventories at the refineries were reduced nearly one-third, and more of the other petroleum products were transferred to the asphalt account. Exports in 1942 were only 38 percent as large as those in 1941.

As in 1941, the tonnage of bituminous rock sold increased more proportionally—43 percent—than did the total tonnage of solid and liquid asphalt sold for paving purposes—10 percent. Although the comparatively low valued products of Texas and Oklahoma supplied the greater increases in sales of bituminous rock, the total value of bituminous rock sold increased 46 percent, and the average value per short ton was 2 percent higher.

NATIVE ASPHALT AND BITUMENS

Bituminous rock.—Sales of rock asphalt by producers in the United States increased 43 percent in quantity—from 654,692 short tons in 1941 to 935,295 tons in 1942—and 46 percent in value—from $2,312,227 to $3,367,279. Prices were higher than in 1941, and the average sales value at the mine increased from $3.53 to $3.60 per ton.

Texas and Oklahoma operators increased their sales from 446,432 tons valued at $1,197,319 in 1941 to 699,572 tons valued at $2,018,822 in 1942. Sales were larger also in California and in Missouri. East of the Mississippi River, producers in Kentucky and Alabama enlarged their sales from 193,887 tons valued at $1,047,529 in 1941 to 207,324 tons valued at $1,228,748 in 1942.

Gilsonite and wurtzilite.—Increased demand in the domestic market raised producers' sales of gilsonite in Utah from 36,407 tons valued at $851,623 in 1941 to 40,041 tons valued at $909,311 in 1942. The average sales price per ton at the mine or railhead decreased from $23.39 to $22.71.

Sales of wurtzilite from Utah decreased from 69 tons valued at $5,343 in 1941 to 37 tons valued at $2,852 in 1942.

Sulfonated bitumen.—Sales of natural sulfonated bitumen from Box Elder County, Utah, were considerably larger in 1942 than in 1941.

Exports.—Exports of natural unmanufactured asphalt amounted to 10,865 short tons valued at $328,660 in 1941 and to 8,941 tons valued at $231,772 in 1942. Increased sales to Canada, Australia,

Digitized by Google

and the United Kingdom did not compensate for decreased exports to Brazil and complete cessation of shipments to Japan and to China.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Production of asphalt by petroleum refineries in the United States decreased 4 percent from 1941. In the East Coast district output decreased 62 percent, because wartime difficulties of transport reduced the total runs of crude petroleum by 26 percent, and higher proportions of the reduced runs were made into residual and distillate fuel oil. Slightly less asphalt was made in refineries of the Indiana-Illinois-Kentucky-etc. district also than in 1941. On the other hand, increased production of asphalt in the other refining districts almost offset the sharp decrease in the East Coast district. The most marked increase in asphalt tonnage was in California, where 50 percent more asphalt was made in 1942 than in 1941.

Production, receipts, stocks, consumption, transfers, losses, exports, and domestic sales of asphalt (exclusive of road oil) at petroleum refineries in the United States in 1942, by districts, in short tons

District	Production	Receipts from other sources	Stocks		Consumption by companies, transfers, losses, and exports	Sales to domestic consumers

Digitized by Google

Stocks.—The heaviest relative drafts on stocks were at East Coast refineries. Stocks were reduced also during 1942 in the Indiana-Illinois-Kentucky-etc., the Oklahoma-Kansas-Missouri, the Louisiana Gulf Coast, and the Rocky Mountain districts. On the other hand, more asphalt was in storage at the end of 1942 in the Appalachian district in Texas, and in California.

Sales.—Sales of petroleum asphalt by refineries to domestic consumers in the United States increased 10 percent in quantity and 17 percent in value from 1941 to 1942; the average value at the refinery increased from $9.72 per short ton to $10.35.

Of the total sold, 7 percent was manufactured from foreign petroleum (imported chiefly from Venezuela and Mexico) in 1942, compared with 25 percent in 1941. Although runs of foreign crude oil to stills decreased 71 percent, sales of petroleum asphalt from this source decreased only 68 percent. Of the foreign crude processed, 17 percent was converted into asphalt in 1941 and 21 percent in 1942. East Coast refineries sold 88 percent of the total asphalt made from foreign crude in 1942 compared with 97 percent in 1941.

Highway and street construction and airport-runway surfacing used (in the form of paving asphalt, paving flux, cut-back asphalts, and asphalt emulsions) 64 percent of the total asphalt sold to domestic consumers by petroleum refineries in 1942 as in 1941. Street and road contracts exceeding $25,000, compiled by Engineering News-Record, show a decrease of 9 percent in value—from $582.8 million in 1941 to $530.5 million in 1942—and of 14 percent in indicated volume if the values are adjusted by the Engineering News-Record index of construction costs. Contracts awarded in New England and 5 Middle Atlantic States decreased sharply and were considerably lower in 14 States lying west of Mississippi River and east of the Rocky Mountains. On the other hand, more roadway was contracted for in 10 Southeastern States and Louisiana in 1942 than in 1941; and in 7 Far Western States a sharp increase in highway contracts occurred.

Total United States	1,764,221	2,133,214

Nevertheless, sales of paving asphalt, used for high-type surfacing, increased 21 percent over 1941. The East Coast district was the only exception to the general increase. Government purchases rather than private contracts apparently caused these increases.

A marked drop in sales of cut-back asphalts by East Coast refineries was the principal factor in the 6-percent decline in total sales of these products. Sales of cut-backs were more than one-third less than in 1941 in the Oklahoma-Kansas-Missouri district also. In other refining districts sales of cut-back asphalts increased markedly, indicating an increase in light highway construction, except on the East coast and in central United States.

Total Texas	141,058	206,274
Louisiana-Arkansas:		
Louisiana Gulf Coast	143,544	172,716
Arkansas and Louisiana Inland	48,507	51,965
Total Louisiana-Arkansas	192,051	224,681
Rocky Mountain	114,739	225,890
California	228,427	439,557
Total United States	1,903,132	1,788,970

More emulsified asphalts were sold in 1942 than in 1941. Petroleum refineries sold 129,006 short tons (30,396,265 gallons) valued at $1,576,840 in 1941 and 118,645 tons (27,955,076 gallons) valued at $1,481,652 in 1942; in addition, 76,830,549 gallons valued at $6,919,102 in 1941 and 86,973,381 gallons valued at $8,996,057 in 1942 were sold by major industrial companies that purchased asphalt from petroleum refineries. Accordingly, total known sales of emulsified asphalts and fluxes increased 7 percent in quantity—from 107,226,814 gallons to 114,928,457 gallons—and 23 percent in value—from $8,495,942 to $10,477,709.

Roofing manufacture made the second-largest demand for asphalt, absorbing 27 percent of the total sales to domestic consumers in both 1941 and 1942. Although shipments of prepared roofing and asphalt siding reported to the Bureau of the Census increased 26 percent—from 44,275,100 squares (revised figure) in 1941 to 55,967,441 squares in 1942—domestic sales of roofing asphalt and roofing flux combined increased only 12 percent—from 1,671,696 to 1,869,458 tons.

Roofing asphalt and flux sold at petroleum refineries to domestic consumers in the United States, 1941–42, by districts, in short tons

FOREIGN TRADE

Imports.—Imports of natural asphalt and bitumen into the United States in 1942 totaled 7,961 short tons valued at $136,054 compared with 13,543 tons valued at $182,723 in 1941. Imports of lake asphalt from Trinidad decreased from 8,593 tons valued at $93,708 in 1941 to 6,122 tons valued at $79,817 in 1942, and imports of grahamite from Cuba decreased from 4,682 tons valued at $83,859 to 1,351 tons valued at $24,741.

Imports of solid petroleum asphalt increased slightly—from 66,352 tons valued at $243,306 in 1941 to 68,638 tons valued at $309,140 in 1942. All the 1941 imports and 66,505 tons (valued at $282,395) of those in 1942 came from Netherlands West Indies.

In addition, 434,839 barrels (79,062 tons) valued at $243,306 of liquid petroleum asphalt, including cut-backs and road oil, were imported in 1941 and 255,934 barrels (46,533 tons) valued at $370,606 in 1942. Mexico supplied all the imports in 1941 and 255,418 barrels (46,439 tons) valued at $369,088 of those in 1942.

Exports.—War blockades and the disruption of normal ocean traffic caused exports of petroleum asphalt from the United States to drop from 224,798 short tons valued at $3,689,502 in 1941 to 85,205 tons valued at $1,645,353 in 1942. The only exceptions to the general decline were in points of special war activity of the United States, such as Panama Canal Zone, Gold Coast, and Nigeria.

DISTRIBUTION BY RAIL

The tonnage of asphalt (natural, byproduct, or petroleum) terminated by class I and class II railroads within the United States decreased from 6,879,488 tons in 1941 to 6,152,459 tons in 1942, according to freight-commodity statistics compiled by the Interstate Commerce Commission. Increased deliveries in the Pacific, Mountain, and West South Central States failed to offset smaller deliveries east of Mississippi River and in the West North Central States.

ROAD OIL

Refinery sales of road oil to domestic consumers decreased 19 percent in quantity in 1942. Only 31,325 barrels valued at $58,371 were manufactured from foreign crude. Of this total 18,858 barrels valued at $28,406 were sold by refineries of the East Coast district, and nearly all the remainder was sold by refineries of the Rocky Mountain district.

SUMMARY

Production of finished hydraulic cements in 1942, the construction year of the war program, advanced to a new record of 185,341,609 barrels—a total that surpassed 1941 output by 11 percent and the former high set in 1928 by 4 percent. The gain over 1941 resulted entirely from the record demand for portland cement as output of natural and other hydraulic cements, which represent only a small percentage of the total, declined slightly. Total shipments from producing mills in 1942 reached a new high volume of 187,809,208 barrels and exceeded production by nearly 2½ million barrels. As a result, stocks of finished cement at mills on December 31, 1942, fell to 17,696,686 barrels, a 12-percent decline from stocks at the end of 1941. Reflecting increased costs of production over 1941, the average mill value of portland cement rose 6 cents to $1.53 per barrel and that for all other hydraulic cements advanced 10 cents to $1.46.

Although private and defense construction had begun to taper off in the latter part of 1941, the mounting volume of construction contracted after the country entered the war in December had almost immediate effect upon the cement industry. Over-all activity, after allowance for seasonal effects, increased rapidly to a peak in the August-October period of 1942. Production of cement advanced from the low monthly volume of the year in February to a peak in October with only minor recessions during June and September. Through November and December output was maintained at a relatively high level in order to replenish the badly depleted stocks. Monthly shipments increased rapidly from February through August and remained at a high level to the end of October. However, in November and December shipments declined at a slightly more than seasonal rate. During January–March stocks of finished cement were built up to a normal level of about 25 million barrels, which was maintained through May. In the June-October period, when ship-

Digitized by Google

ments greatly exceeded production, stocks declined rapidly to a low on October 31 of slightly less than 11 million barrels, but by the end of December these had been restored approximately halfway to the customary level.

Requirements exceeded supplies in some sections of the country, and cement had to be brought in from relatively distant plants. However, there were few shipments of large quantities for unusually long distances. Shortages developed during 1942 in the Southeastern States, Texas, and Washington. Temporary shortages were apparent in Kansas and Nebraska.

The strong demand for cement originated principally in the large volumes of military and industrial construction started in 1942. As measured by Federal Reserve Board indexes (1923–25=100), based upon data of the Dodge Corporation, the value of construction contracts awarded in 1942 reached a new high of 166 compared with 122 in 1941 and 135, the former record, in 1928. The index for residential building declined from 89 in 1941 to 82 in 1942, whereas that for all other construction rose from 149 in 1941 to 235 in 1942. Engineering construction, which requires large quantities of cement, increased 59 percent over 1941, according to values of contracts reported by Engineering News-Record. The area of concrete pavement contracted for in 1942, as recorded by the Portland Cement Association, was 56

Digitized by Google

percent greater than in 1941 and totaled nearly 132 million square yards. Airport paving was slightly more than treble the 1941 area and represented nearly three-fourths of the total pavement contracted in 1942, compared with slightly more than one-third in 1941. Road, street, and alley paving fell nearly one-third below the 1941 volume.

Distribution of consumption changed sharply in 1942, as indicated by the foregoing data. Direct military construction doubtless consumed most of the supply. In this category, the large volume of airport construction, coupled with the greater thicknesses of runways required to support the heavy planes, probably consumed more cement than any other type of construction. After military uses, the probable order of consumption was in construction of industrial plants and facilities, highways, and residential building. The first year of war also effected a marked change in location of cement consumption in the country (see fig. 2). As indicated by destinations of shipments from mills, consumption increased sharply over 1941 in the Southern and Rocky Mountain States and gained moderately in the Middle and Pacific States but declined in the Northeastern States.

The first direct war control on the cement industry was the General Maximum Price Regulation of the Office of Price Administration, effective May 11. This order froze prices of cement at the highest selling value, f. o. b. plant, obtained during March 1942. Cement prices were removed from the general order by Maximum Price Regulation 188, which was effective August 1 and continued the March prices as maximum. With regard to cement prices, this order was superseded by Maximum Price Regulation 224, which applied only to cement and was effective September 23. Under the last regulation, prices on shipments within ordinary shipping radius of the mill were set at the maximum value obtained during the March 1–15 period, whether on a mill or delivered basis, plus any increase in freight rates since March 17. However, in order to insure adequate supplies in deficient areas, prices on shipments outside the normal shipping area of a mill were placed on an average dollars and cents f. o. b. basis determined for each Bureau of Mines district. For all districts other than California and Oregon and Washington the base was equal to 95 percent of the average net mill realization during 1941. In the two excepted districts the base was set at 95 percent of average net mill realization for the first quarter of 1942. This regulation provided for absorption of the extra and relatively high transportation costs by the consuming Government agencies.

As a means of increasing production and conserving grinding medium and power, similar emergency alternate specifications for three types of portland cement were formulated and approved early in June by the Federal Government and American Society for Testing Materials. War Production Board Limitation Order L–179, effective August 23, restricted manufacture of portland cement to the three types—general-purpose, moderate-heat, and high-early-strength—set forth in the emergency specifications. The order also prohibited assignment of storage bins for the exclusive use of any customer and required that all testing be done by the National Bureau of Standards or a Standards-approved laboratory. Twelve large dams in the Southern and Western States and oil-well cements were exempted from provisions of the orders.

Digitized by Google

On February 16, 1943, an amendment to this general limitation order removed the ban upon assignment of bin space to customers and no longer required that tests be done by an approved laboratory.

In addition to direct controls, the cement industry was affected by war restrictions on construction. The first of these, War Production Board Conservation Order L–41 of April 9 and its more restrictive revision of September 7, brought a virtual halt to all nonessential public and private construction as a means of assuring adequate labor and material supplies for necessary building. After the middle of 1942, the growing shortage of labor and raw materials forced recognition that construction was out of balance with other phases of the war

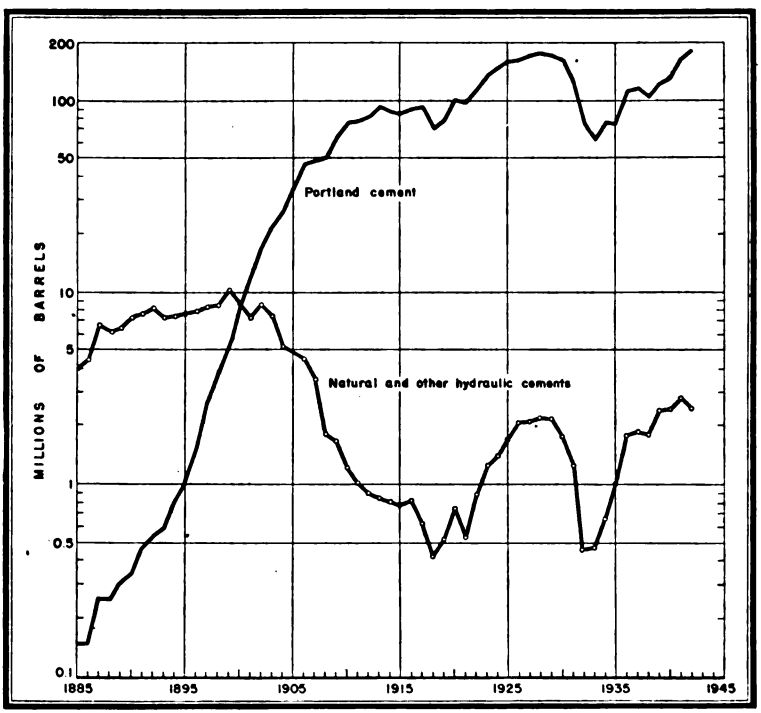

FIGURE 1.—Trends in production of hydraulic cements in the United States, 1885–1942.

program and that the country was being overbuilt. Consequently, the War Production Board on October 22 established the Facility Clearance Board and the Facility Review Committee to review construction already contracted and under way and also to approve all proposed construction for essentiality. By the end of 1942, stop orders had been issued on nearly 1¼ billion dollars of contracts, of which much of the volume was for engineering construction that would have required large quantities of cement.

Since its inception in the early 1870's the portland cement industry has shown a remarkable rate of growth. By 1888 annual production had increased to 250,000 barrels, and from that time output gained

Digitized by Google

rapidly in each year through 1913, when 92,097,131 barrels was produced. However, as shown in figure 1, the rate of increase flattened appreciably after 1910, and from 1913 through 1918 the industry suffered its first recession. The uptrend was resumed in 1919, and except for a minor setback in 1921 it continued at a substantial rate through 1928. In the depression of the early 1930's production slumped to 63,473,189 barrels (in 1933); and although recovery since then has been irregular, the over-all improvement, to the record output of 1942, has been rapid. Natural cement was first made in the United States near Chittenango, N. Y., in 1818. Combined annual production of it and miscellaneous hydraulic cements other than portland showed a generally rising trend to the record output of 10,203,179 barrels in 1899. Demand for portland exceeded that for other hydraulic cements for the first time in 1901, and as it continued to increase, demand for other cements declined to a low of 432,966 barrels in 1918. Since then, annual production of hydraulic cements other than portland showed moderate recovery through 1928 followed by a sharp decline through 1932 and subsequent recovery to the 1941 output of 2,875,962 barrels.

PORTLAND CEMENT

PRODUCTION, SHIPMENTS, AND STOCKS

As annual production of portland cement represents about 99 percent of the total output of all hydraulic cements, the general conditions affecting and the activity of the portland cement industry during 1942 were the same as those given in the preceding summary.

Location of war construction in 1942 effected marked changes in the quantities of portland cement produced in the various States. The record output of 1942 was obtained from 155 active mills in 35 States and Puerto Rico. Compared with 1941, production increased in 25 States and Puerto Rico, declined in 6 States, and was relatively unchanged in 4. Exceptional gains of more than one-third were recorded for Kansas, Oklahoma, South Dakota, Washington, and Puerto Rico. Ranking States in 1942, in order of output, were Pennsylvania, California, Texas, New York, and Michigan. Manufacture of cement ceased in New Jersey in 1942, and output declined sharply from 1941. Production was higher than in 1941 in all Bureau of Mines districts except New York and Maine, for which a small decline was recorded. The largest proportional gains were in the Western Missouri-Nebraska-Kansas-Oklahoma-Arkansas, Oregon-Washington, and Puerto Rico districts.

Shipments from mills during 1942 exceeded production in all districts except the Eastern Pennsylvania-New Jersey-Maryland, New York-Maine, Michigan, and Puerto Rico. As a result, these were the only districts in which stocks of finished cement at mills on December 31, 1942, were greater than at the end of 1941.

End-of-month stocks at mills of both finished portland cement and clinker were relatively stable in the 1935–39 period at average levels of approximately 22½ and 6 million barrels, respectively. However, beginning with 1940, monthly stocks have shown an increasing range of fluctuation in each year through 1942. During January–March 1942 production exceeded shipments, and stocks of finished cement were rebuilt from a relatively low condition at the end of 1941 to 25,832,000 barrels on March 31, or slightly above the customary level. Stocks declined somewhat to the end of May, and then as shipments greatly exceeded production they fell rapidly to a low of 10,624,000 barrels on October 31. The strong demand for cement and the prohibition of assignment of storage space to customers were the principal factors causing this badly depleted condition. A declining demand during November and December enabled producers to replenish stocks approximately halfway to the customary level by the end of 1942. On December 31 stocks of finished cement were 13 percent below those at the end of 1941.

Clinker stocks in 1942 followed essentially the same pattern as stocks of finished cement, except that recovery from the depleted condition at the end of October was less marked. On December 31 stocks were far below the customary level and were 23 percent lower than at the end of 1941.

Stocks of finished portland cement and portland-cement clinker at mills in the United States on Dec. 31, and yearly range in end-of-month stocks, 1938–42

		Dec. 31 (barrels)	Range

[1] Does not include Puerto Rico, where production began in 1939.
[2] Revised figure.

DOMESTIC CONSUMPTION

Consumption of portland cement in States and regions, as indicated by destinations of shipments in 1942, underwent many changes. On a regional basis selected with reference to areas of cement consumption as well as other economic and geographic factors, consumption increased markedly in the Southern and Rocky Mountain States but gained only moderately over 1941 in the Middle and Pacific States. In the Northeastern States consumption declined slightly from 1941.

As shown by figure 2, in which relative rates of gain or loss may be compared readily by slopes of the curves from year to year, consumption of cement declined sharply from the late 1920's to 1933 in all regions except the Rocky Mountain States, where the decline ended in 1932. From these low points there have been irregular general

Digitized by Google

uptrends in all regions except the Southern States, in which the rising trend has persisted each year. The recovery has been marked in the Southern, Rocky Mountain, and Pacific regions, and it is notable that consumption in these areas in recent years has risen appreciably above the levels attained in the late 1920's. The higher rate and better recovery are attributable to the construction of large power and flood-control dams and, in 1942, to the erection of large war plants and facilities and military establishments in the areas. Consumption of cement in the Northeastern and Middle regions has recovered only moderately from the low points of 1932, and in 1942 the rate was well below the average volumes consumed during 1927–29. States in the regions

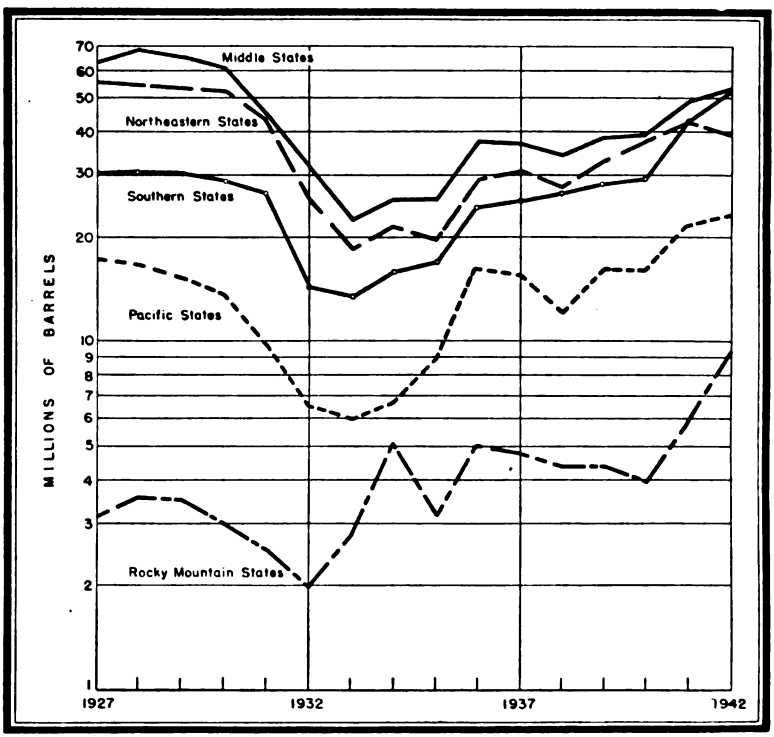

FIGURE 2.—Trends of indicated consumption of portland cement in the United States, 1927–42, by regions.

shown on figure 2 are as follows: Northeastern—Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; Southern—Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia; Middle—Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; Rocky Mountain—Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Utah, and Wyoming; Pacific—California, Oregon, and Washington.

Comparison of indicated cement consumption by States in 1942 and 1941 illustrates the striking effects that location of war construction had on the distribution of consumption. In 1942 consumption increased in 28 States and declined in 20 States and the District of Columbia. The quantities consumed during 1942 in Arkansas, Kansas, Nebraska, Nevada, and South Dakota were more than double the 1941 volumes. Ranking States, in order of consumption, were California, New York, Texas, and Pennsylvania.

The table listing destinations of monthly shipments of portland cement was compiled from the regular monthly reports of producers.

Destination of shipments of finished portland cement from mills in the United States, 1940–42, by States

Destination	1940 (barrels)	1941 (barrels)	1942	
			Barrels	Percent of change from 1941
Alabama	1,458,811	2,491,851	3,237,883	+29.9

LOCAL SUPPLIES

Of the 35 producing States in 1942, more portland cement was produced than consumed internally in 17 and production was less than requirements within the State in 18. Puerto Rico consumed more cement than was produced. Owing to the large aggregate capacity of mills in the State, the greatest surplus was recorded for Pennsylvania. These data, however, do not show areas or States in which a definite shortage of cement existed, because parts of any State commonly are supplied from mills of a neighboring State.

The total surplus of the producing States was distributed as follows: In 1941—to non-cement-producing States, 16,880,678 barrels, and to foreign countries, Alaska, Hawaii, and unspecified destinations, 5,919,919 barrels; in 1942—to non-cement-producing States, 17,908,965 barrels, and to foreign countries, Alaska, Hawaii, and unspecified destinations, 6,930,952 barrels.

Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1941–42, in barrels

TRANSPORTATION

Methods and means of shipping portland cement from producing mills have changed considerably in recent years. Because of conditions imposed by the war, the changes from 1941 to 1942 probably were more marked than those between any other successive years. As shown in figure 3, there was a growing use of truck haulage from 1934, the first year for which data are available, to 1941. However, in 1942, the percentage hauled by truck decreased from 1941, owing undoubtedly to war restrictions on tires and gasoline. Rail shipments, which represent by far the major part of total cement movements, showed a small decrease in percentage from 1934 to 1941

Digitized by Google

but in 1942 regained most of the loss and returned nearly to 1934 proportions. Shipments by boat constitute only a small part of the total and have declined in percentage from 1934.

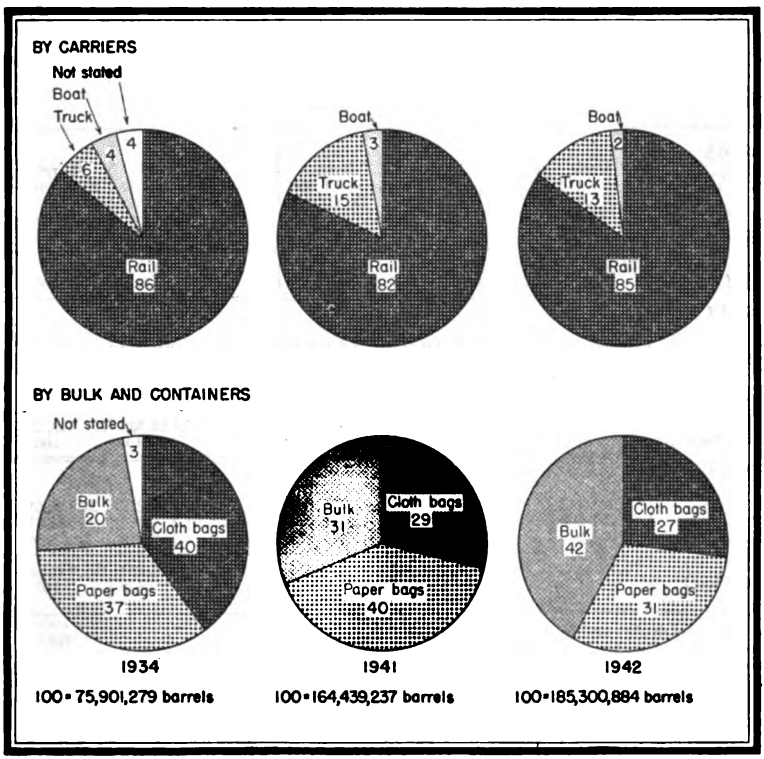

FIGURE 3.—Percentage distribution of portland-cement shipments from mills in 1934, 1941, and 1942, by types of carriers and by bulk and types of containers.

Distribution of cement shipments by bulk and types of containers in 1942 from 1941 differed considerably and differed also from the practice in 1934 and 1928. In 1928, only 2.4 percent of total shipments were made in bulk, and the rest were made in containers. Cloth bags apparently were the most popular containers used in 1928, although no specific data are available. After 1928 the proportions of bulk shipments increased rapidly to 20 percent in 1934 and 31 percent in 1941. Owing to the scarcity of packaging materials and to the fact that much of the construction in 1942 comprised large projects requiring much cement, the proportion of bulk shipments jumped to 42 percent of the total in 1942. Although the percentage of total shipments in cloth bags in 1934 was slightly higher than that in paper bags, by 1941 paper-bag shipments represented 40 percent of the total, compared with only 29 percent in cloth. As a result of the paper shortage in 1942 and the greater demand for bulk cement, the proportion shipped in paper declined to less than one-third of the total and was only slightly greater than the percentage shipped in cloth. The proportion shipped in cloth declined only slightly from 1941.

[1] Includes steel drums and iron and wood barrels.
[2] Includes shipments for Puerto Rico.
[3] Includes cement used at mills by producers as follows—1940: 118,709 barrels; 1941: 196,765 barrels; 1942: 181,642 barrels.
[4] Less than 0.05 percent.

PRICES

Reflecting increased costs of production, the average selling value of all portland cement at the mill, excluding cost of containers and cash discounts, advanced 6 cents over 1941 to $1.53 per barrel in 1942. This average value, as computed from reported data, is higher than an average value for general-purpose cement because it includes special cements with relatively high prices.

Average mill value per barrel, in bulk, of portland cement in the United States, 1938–42

1938 [1]	$1.45	1941	$1.47
1939	1.47	1942	1.53
1940	1.46		

[1] Does not include Puerto Rico, where production began in 1939.

A study [1] of wholesale and retail prices of building materials states that portland cement generally is sold under the multiple basing-point price system, in which basing points are usually producing centers. The average wholesale and retail prices of portland cement in September 1939 in the 26 cities surveyed was $2.01 and $2.67 per barrel, respectively, an average spread of 33 percent. In general, the highest prices were reported in the West South Central and Rocky Mountain States, and the lowest were in the East North Central area. Both wholesale and retail prices showed fairly wide geographical variations.

[1] Temporary National Economic Committee, Geographical Differentials in Prices of Building Materials. Mono. 33, 1940, pp. 89–103.

CAPACITY OF PLANTS

Aggregate capacity of all portland cement plants increased slightly over 1941 and was utilized at 73.5 percent of the total to produce the record output in 1942. Capacity data for 1942 include 155 active plants and 1 inactive plant that produced or shipped since the beginning of 1935. Figures for 1 plant each in Indiana and New Jersey that ceased operations and were dismantled in 1942 also are included. The data were compiled from reports of producers, who were asked to make allowances for repairs and other unavoidable shut-downs, and are expressed in terms of finished portland cement so as to cover the limiting factor in production at each mill, whether it be in the raw-grinding, burning, or finish-grinding departments. During 1942, operators in the Texas, Virginia-Tennessee-Alabama-Georgia-Florida-Louisiana, California, and Puerto Rico districts used the largest percentage of installed capacity.

Portland-cement-manufacturing capacity of the United States, 1941–42, by producing districts

District	Estimated capacity (barrels)		Percent of capacity utilized	
	1941	1942	1941	1942
Eastern Pennsylvania, New Jersey, and Maryland	45,274,000	45,554,000	68.5	69.2
New York and Maine	17,244,000	17,626,000	69.6	66.4
Ohio, western Pennsylvania, and West Virginia	26,574,000	26,243,000	57.0	59.3
Michigan	14,055,000	14,055,000	67.5	75.5
Wisconsin, Illinois, Indiana, and Kentucky	28,267,000	28,662,000	57.4	65.0
Virginia, Tennessee, Alabama, Georgia, Florida, and Louisiana	24,512,000	24,612,870	81.5	88.6
Eastern Missouri, Iowa, Minnesota, and South Dakota	22,475,000	20,936,622	52.8	61.3
Western Missouri, Nebraska, Kansas, Oklahoma, and Arkansas	16,598,000	16,915,000	59.7	81.1
Texas	12,352,000	13,200,154	78.4	91.9
Colorado, Montana, Utah, Wyoming, and Idaho	5,815,000	5,925,000	68.0	73.8
California	26,290,000	27,071,302	75.8	86.3
Oregon and Washington	7,440,000	7,440,000	58.9	78.8
Puerto Rico [1]	463,000	610,000	99.9	109.3
	247,359,000	248,850,948	66.3	73.5

[1] Includes a new plant in Puerto Rico (September 1942 first month in production).

It is noteworthy that of the 155 plants active in 1942, 83, or 54 percent of the total, had an installed annual capacity between 1,000,000 and 1,999,000 barrels.

Distribution of portland-cement plants in the United States in 1942, according to annual capacity

Estimated annual capacity, barrels:	*Number of plants*
Less than 1,000,000	37
1,000,000 to 1,999,000	83
2,000,000 to 2,999,000	25
Between 2,999,000 and 10,000,000	11
	156

Percentage of capacity used in each month of 1942 was well above that for the corresponding month of 1941. In 1942 the monthly percentage utilized increased steadily from the low of 57 in February to the high of 87 in September and October, from which it fell to 67 in December.

Digitized by Google

Percent of capacity used in the finished portland-cement industry in the United States, 1941–42

Month	Monthly		12 months ended—		Month	Monthly		12 months ended—	
	1941	1942	1941	1942		1941	1942	1941	1942
January	42	59	53	67	July	75	80	60	71
February	43	57	54	69	August	77	85	61	73
March	50	61	56	69	September	78	87	62	73
April	59	69	57	70	October	79	87	64	73
May	69	77	57	71	November	73	80	65	74
June	74	79	58	71	December	65	67	66	74

Capacity of portland-cement plants in the United States, 1940–42, by processes

Process	Capacity						Percent of capacity utilized			Percent of total finished cement produced		
	Thousands of barrels			Percent of total								
	1940	1941	1942	1940	1941	1942	1940	1941	1942	1940	1941	1942
Wet	122,266	121,065	122,432	48.1	48.9	49.2	55.4	70.3	77.7	52.0	51.9	52.1
Dry	131,879	126,294	126,419	51.9	51.1	50.8	47.4	62.5	69.3	48.0	48.1	47.9
	254,145	247,359	248,851	100.0	100.0	100.0	51.2	66.3	73.5	100.0	100.0	100.0

Although in recent years the aggregate capacity of dry-process plants was slightly greater than that of wet-process plants, it seems significant that in recent years the wet-process capacity has been utilized more fully than the dry-process capacity.

CLINKER PRODUCTION

Production of clinker, the intermediate product of the industry, gained 11 percent over 1941. Stocks at mills on December 31, 1942, were unusually low and were 23 percent below those at the end of 1941.

Portland-cement clinker produced and in stock at mills in the United States, 1941–42, by processes, in barrels of 376 pounds [1]

Process	Plants		Production		Stock (Dec. 31)	
	1941	1942	1941	1942	1941 [2]	1942 [3]
Wet	90	90	84,568,000	93,817,195	2,499,496	1,722,266
Dry	65	65	79,061,000	87,450,266	2,075,033	1,787,070
	155	155	163,629,000	181,267,461	4,574,528	3,509,336

[1] Compiled from monthly estimates of the producers.
[2] Revised figures.
[3] Subject to revision.

PRODUCTION ACCORDING TO RAW MATERIALS

The relationship of the percentages of total output classified according to kinds of raw materials changed little in 1942 from 1941.

As indicated by the data available, mills employing cement rock and limestone have furnished approximately the same proportion of total output each year since 1912. However, in the 1900–1912

Digitized by Google

period there was a steady decline in the annual percentages supplied from these mills, which are mainly in eastern Pennsylvania and New Jersey. The decline was caused by the gradual spreading of the industry into all sections of the country and the concomitant erection of new plants using limestone and clay or shale as raw materials. Mills employing the latter group of raw materials supplied a generally rising percentage of total production until about 1926, from which, up to the present time, the annual proportion has fluctuated in a relatively narrow range. Since 1899, the proportion of total output of cement derived from marl and clay has declined more or less regularly to the present low percentages. Cements derived from slag and limestone have represented a relatively small and declining part of total production in recent years.

Production and percent of total output of portland cement in the United States, 1898–1914, 1926, 1929, 1933, 1935, 1941, and 1942, according to raw materials

Year	Cement rock and pure limestone		Limestone and clay or shale		Marl and clay		Blast-furnace slag and limestone	
	Barrels	Percent	Barrels	Percent	Barrels	Percent	Barrels	Percent
1898	2,764,694	74.9	365,408	9.9	562,092	15.2		
1899	4,010,132	70.9	546,200	9.7	1,095,934	19.4		
1900	5,960,739	70.3	1,034,041	12.2	1,454,797	17.1	32,443	0.4

[1] Includes output of 2 plants using oystershells and clay in 1926; 3 plants in 1929, 1933, and 1935; and 4 plants in 1941 and 1942.

RAW MATERIALS

Approximately 58,853,443 short tons of raw materials (exclusive of fuels and explosives) entered into the manufacture of 182,781,184 barrels (34,362,863 short tons) of portland cement in 1942, an average of 644 pounds to a 376-pound barrel of finished cement. The totals for 1942, with corresponding figures for 1941 (in parentheses), follow: 47,657,208 tons of limestone and cement rock (42,733,707 tons); 5,181,582 tons of clay and shale (4,726,192 tons); 809,371 tons of slag (659,201 tons); 903,360 tons of marl (1,066,635 tons); 1,248,448 tons of gypsum (1,035,179 tons); and 3,053,474 tons of other materials such as oyster shells, sandstone, sand, cinders, fluorspar, iron ore, diatomaceous shale, pumicite, fuller's earth, bentonite, silica, quartz, ashes, pyrite cinder and ore, roll scale, calcium chloride, and hydrated lime (2,534,339 tons).

FUELS AND POWER

Fuels.—The fuel-oil shortage in the Eastern States in the latter half of 1942 forced cement plants to convert from oil to coal wherever possible. As a result, and because of increased production, the quantity of coal consumed by the portland-cement industry increased markedly over 1941. However, total consumption of fuel oil declined only slightly owing to the greater output of cement in areas where oil was not restricted. Consumption of natural gas by the industry was well above 1941. At the end of 1942, greatly increased requirements for natural gas for industrial and heating purposes caused local shortages in Kansas and Nebraska, and mills in that area had difficulty in obtaining adequate supplies.

Finished portland cement produced and fuel consumed by the portland-cement industry in the United States, 1941–42, by processes

Process	Finished cement produced			Fuel consumed [1]		
	Plants	Barrels of 376 pounds	Percent of total	Coal (short tons)	Oil (barrels of 42 gallons)	Natural gas (cubic feet)
1941						
Wet	90	85,153,919	51.9	[2] 3,325,823	2,090,700	34,045,968,833

[2] Includes 107,663 short tons of anthracite and 7,462,434 short tons of bituminous coal.

Electric power.—Ten percent more electric power was consumed by portland cement mills in 1942 than in 1941. However, the average quantity used per barrel of finished cement produced decreased slightly from 22.2 kilowatt-hours in 1941 to 21.9 kilowatt-hours in 1942.

Electric energy used at portland-cement-producing plants in the United States, 1941–42, by processes, in kilowatt-hours

Process	Electric energy used						Finished cement produced	Average electric energy used per barrel of cement produced

SPECIAL CEMENTS

In addition to the standard or general-purpose portland cement that constitutes most of the total production, several special varieties are made. Of these, the low- and moderate-heat and high-early-strength types are the most important, and demand for them has increased sharply in recent years. Demand for the other special cements was considerably below that in 1941.

Prepared masonry mortars.—Production of these mixed materials from 48 plants totaled 2,067,370 barrels and shipments 2,079,015 barrels, valued at $3,115,799, an average of $1.50 per barrel. These data are not included in the statistics of this chapter, but the portland cement used in their manufacture is included.

NEW DEVELOPMENTS

To conserve power and grinding equipment and to increase production, emergency alternate specifications [2] approved early in June, reduced the types of portland cement from 5 to 3—general-purpose, moderate-heat, and high-early-strength. These specifications differed from those in effect before the emergency by limiting the maximum specific surface area to not more than 2,000 square centimeters per gram and lowering the minimum requirement to 1,500 square centimeters per gram; by raising the permitted expansion in the autoclave to 1 percent; by eliminating the 28-day test and requiring tests only

Am. Soc. for Testing Materials, Emergency Alternate Specifications for Portland Cement, A. S. T. M.: Designation EA-C-150-Type I; EA-C-150-Type II; and EA-C-150-Type III; June 6, 1942.

Digitized by Google

at 3 and 7 days; and by permitting the use of TDA in all three types and of vinol resin in the general-purpose and moderate-heat types.

Results of a study [3] on hydrated calcium aluminates yielded fundamental information on phase solubilities and equilibria of the CaO–Al_2O_3–H_2O system.

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

Production of the natural, masonry (natural), and puzzolan cements declined slightly from 1941. Output of these cements had advanced from 1938 to 1941, in which year annual output was higher than at any time since 1907. In 1942 producers reported consumption of 36,808 short tons of coal and of gas equivalent to 70 tons of coal.

Shipments also declined in 1942 from 1941, and, as production exceeded shipments, stocks on December 31, 1942, were 26 percent greater than at the end of 1941.

Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1938–42

Year	Production		Shipments		Stock (Dec. 31)
	Active plants	Barrels (376 pounds)	Barrels (376 pounds)	Value	Barrels (376 pounds)
1938	12	1,820,795	1,867,949	$2,725,776	373,816
1939	12	2,439,110	2,405,135	3,361,724	239,938
1940	12	2,534,566	2,514,597	3,386,801	259,868
1941	12	2,875,962	2,926,203	3,967,567	[1] 199,355
1942	11	2,560,425	2,508,324	3,668,169	251,466

[1] Revised figure.

FOREIGN TRADE

Because of wartime restrictions, no figures on imports and exports can be published. However, foreign trade of the United States in cement has little effect on the domestic industry; consequently, it is believed that lack of these data will not detract appreciably from the value of this chapter. Foreign-trade figures will be released at the termination of the war so as to preserve the continuity of the statistical record.

Imports.—During the 1935–39 period, imports of hydraulic cement ranged from 619,404 barrels valued at $615,866 (c. i. f. port of shipment) in 1935 to 1,913,853 barrels at $1,860,543 in 1939 and had an annual average of 1,544,700 barrels at $1,345,478. This average represents only 1.4 percent of the average annual consumption of 108,934,353 barrels in the United States during the 1935–39 period. In 1939, the last year with an undisturbed flow of imports, about 97 per cent of total imports of cement originated in Europe, more than half coming from Belgium and about a fourth from Denmark. Following the outbreak of war in Europe in 1939, the conquering of Denmark, Norway, Belgium, and France by Germany in the first half of 1940, and the blockade of Europe by the British Navy, cement imports during 1940 slumped to 538,060 barrels valued at $506,191.

[3] Wells, Lansing S., Clarke, W. F., and McMurdie, H. F., Study of the System CaO–Al_2O_3–H_2O at Temperatures of 21° and 90°C: National Bureau of Standards Jour. of Research, vol. 30, May 1943, pp. 367–409.

Digitized by Google

This quantity represents only 0.4 percent of the apparent consumption (131,734,848 barrels) in the United States in 1940. Importation virtually ceased in 1941, during the first 9 months of which 43,110 barrels valued at $57,914 were brought into the country. The monthly rate of import in 1941 was 4,790 barrels, compared with 44,838 barrels per month during 1940, a decline of 89 percent. It seems evident that imports in 1942 undoubtedly were insignificant.

Exports.—Exports in the 1935–39 period ranged from 334,673 barrels valued at $886,560 in 1936 to 1,146,339 barrels at $2,352,693 in 1939 and had an annual average of 566,778 barrels at $1,318,248. This average is only 0.5 percent of average annual domestic shipments of cement (107,956,430 barrels) in the United States during 1935–39. In 1940, the last year for which complete data are available, exports increased 45 percent over 1939 to 1,667,595 barrels valued at $3,294,118, a quantity representing only 1.3 percent of domestic shipments (132,864,383 barrels) from mills in the United States during the same year. Exports in 1940 were distributed as follows: 73 percent (1,212,909 barrels) to North American countries (including the West Indies), of which more than half went to Panama (Republic and Canal Zone); 26 percent (431,904 barrels) to South American countries, of which three-fourths went to Venezuela; and the remaining 1 percent was distributed to countries in Europe (452 barrels), Asia (7,810 barrels), Africa (14,108 barrels), and Oceania (412 barrels). Exports during the first 9 months of 1941 totaled 1,757,172 barrels valued at $3,793,511, a monthly rate of 195,241 barrels or 40 percent higher than the 138,966 barrels per month exported in 1940.

Shipments of domestic hydraulic cements to noncontiguous territories of the United States in 1940, the last year for which data were published, were nearly double those in 1939 and totaled 1,461,940 barrels valued at $2,628,402, of which 47 percent was sent to Hawaii and 46 percent to Puerto Rico. These 1940 shipments represent 1.1 percent of total domestic shipments from mills in the same year.

In 1942, both exports and shipments to noncontiguous countries undoubtedly were greater than in 1941, owing to such factors as increased construction of military and naval facilities by the United States in offshore locations and foreign countries, the accelerated construction of the Pan American Highway, and the continued blockade of European producers from world markets for cement. Partly offsetting these factors, the Army, Navy, and other governmental agencies performing construction work outside the United States have tended to use local or the nearest source of supply of cement to conserve shipping space.

WORLD PRODUCTION

World production of hydraulic cements in 1942, based upon the meager data available, is estimated at approximately 72 million metric tons.

Output in most of the countries of the Western Hemisphere doubtless was higher in 1942 than 1941, owing principally to the increased construction of war plants, military facilities, and the Pan American highway. However, in some countries production was below the 1941 level, as in Brazil, where a fuel shortage reportedly curtailed production.

Digitized by Google

In all European countries, except Spain, production probably was curtailed markedly because of labor and fuel shortages. Military uses undoubtedly consumed most of the product in these countries, and civilian and industrial consumption was kept at a bare minimum as was indicated by the regulation in Germany requiring approval of all purchases exceeding 10 sacks.

In most of the Mediterranean and Near-Eastern countries and in India and Australia production probably gained markedly over 1941, whereas output in the Far Eastern countries declined somewhat. Production in countries in southern and eastern Africa no doubt increased over 1941.

World production of hydraulic cements, 1937–42, by countries, in metric tons [1]

GENERAL CONDITIONS

Sales of crushed and dimension stone combined were 7 percent greater in 1942 than in 1941 and attained an all-time high record of 195,884,490 short tons. The total value of sales (which, for the first time in history, exceeded $200,000,000) was 5 percent greater than in 1941. The gains, however, were confined almost exclusively to crushed and broken stone because wartime construction requires very small quantities of building stone. Sales of dimension stone (exclusive of slate) were 31 percent lower in quantity and 22 percent in value. The crushed-stone industry, on the other hand, gained 7 percent in quantity and 8 percent in value. The trends in these two great branches of the stone industries were the same as in 1941, but the downward trend of dimension-stone sales was accelerated, whereas the upward movement of crushed stone was retarded.

The present chapter follows the general plan inaugurated in 1938, whereby the data on dimension stone are separated from those on crushed stone, except in the introductory general tables.

The tables of this report give the quantities sold or used by producers and the values f. o. b. quarries and mills insofar as these figures are obtainable. Stone quarried and used by producers is considered as sold and is included in the statistics of sales. The data, however, do not include stone made into abrasives (such as grindstones) or that used in making lime and cement. These materials are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following tables show the total sales of stone by kinds, uses, and States:

DIMENSION STONE

Dimension stone and crushed stone are so diverse in character and use that they are considered in separate sections of this chapter. The term "dimension stone" is applied to blocks or slabs of natural stone, most of which are cut to definite shapes and sizes. The principal uses of dimension stone are for construction of masonry walls and for memorials. Crushed and broken stone, on the other hand, consists of irregular fragments or grains, sized chiefly by mechanical screening or air separation. The principal uses are as roadstone, concrete aggregate, railroad ballast, furnace flux, and a great variety of industrial applications that have little or no relation to masonry construction.

Dimension-stone producers may be divided into three main groups upon the basis of plant operation. The first group quarries stone and sells it as rough blocks or slabs; the second quarries stone and also manufactures it into finished products; and the third buys sawed slabs or rough blocks of stone and manufactures them into finished products but does not operate quarries. The Bureau of Mines statistical canvass covers the first and second groups, but as the third group comprises manufacturers rather than quarrymen it is canvassed by the Bureau of the Census. Bureau of Mines statistics are compiled from reports of quantities and values of original sales; hence they include some material sold as rough blocks and some sold as finished products.

Total sales of dimension stone in 1942 declined 32 percent in quantity and 24 percent in value compared with 1941. These figures include slate, but details of the slate industry are given in the separate chapter on Slate. Basalt in the form of rubble and sandstone used for rough construction and rubble made gains in quantity, but all varieties of stone suffered declines in value of sales that ranged from 7 percent for basalt to 43 percent for limestone.

The following table presents salient statistics for 1941 and 1942.

Dimension stone sold or used by producers in the United States, 1941–42, by kinds and uses

Kind and use		1941	1942	
			Total	Percent of change
Granite:				
Building stone:				
Rough construction	short tons	167,440	36,380	−78.3
Value		$208,253	$132,276	−55.6
Average per ton		$1.78	$3.64	+104.5
Cut stone, slabs, and mill blocks	cubic feet	736,730	413,180	−43.9
Value		$1,853,203	$1,030,223	−44.4
Average per cubic foot		$2.52	$2.49	−1.2
Rubble	short tons	277,950	215,730	−22.4
Value		$349,739	$404,460	+15.6
Monumental stone	cubic feet	2,576,550	2,442,630	−5.2
Value		$7,489,197	$7,092,572	−5.3
Average per cubic foot		$2.91	$2.90	−.3
Paving blocks	number	2,384,110	1,986,910	−16.7
Value		$255,276	$188,830	−26.0
Curbing	cubic feet	528,420	200,540	−62.0
Value		$585,808	$232,392	−60.3
Total:				
Quantity	approximate short tons	782,120	522,170	−33.2
Value		$10,831,476	$9,080,753	−16.2

BUILDING STONE

The use of stone as a material of construction predates the most ancient historic records, and building stone is still the principal form in which dimension stone is sold. The following table gives the quantity and value of each kind of stone used for construction in 1942.

Building stone sold or used by producers in the United States in 1942, by kinds

Kind	Rough				Finished				Total	
	Construction		Architectural		Sawed [1]		Cut [1]			
	Cubic feet	Value	Cubic feet	Value	Cubic feet	Value	Cubic feet	Value	Cubic feet	Value
Granite	580,610	$132,276	81,660	$86,736	237,320	$556,687	94,180	$386,800	993,790	$1,162,499
Basalt	59,150	12,652							59,150	12,652
Marble			58,800	111,722	66,650	315,129	153,010	1,140,885	278,460	1,567,736
Limestone	1,332,570	209,313	866,540	257,212	187,370	132,724	838,020	1,192,318	3,224,500	1,791,567
Sandstone	1,087,290	174,730	156,950	178,073	78,940	108,739	28,720	105,049	1,351,900	566,591
Miscellaneous	536,450	825,116							536,450	825,116
	3,596,070	1,354,087	1,163,970	633,743	570,280	1,113,279	1,113,930	2,825,052	6,444,250	5,926,161

[1] For granite, sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.

GRANITE

Sales of granite in the form of dimension stone declined 33 percent in quantity and 16 percent in value in 1942 compared with 1941. Rough-construction building stone declined greatly, although dressed stone gained moderately. Sales of memorial granite were a little lower than in 1941. The value per cubic foot of dressed building stone declined from $4.41 in 1941 to $2.85 in 1942, and the value of dressed monumental stone increased from $6.35 to $7.22. Sales of paving stones and curbing declined greatly. Building stone, paving stones, and curbing are all associated closely with types of construction that receive very little encouragement in a time of war. Sales of monumental stone, however, depend principally on buying power, which was high in 1941, and their moderate declines may be attributed to shortage of labor and materials rather than to recession in market demands.

[1] Through the kindness of the Granite Manufacturers' Association, Barre, figures covering the entire granite industry of the Barre district are given in this table to supplement figures of sales reported by quarrymen.

BASALT AND RELATED ROCKS (TRAP ROCK)

Because of its dark color, basalt is not used extensively for building. The tonnage sold in 1942 was somewhat higher than in 1941, but the value per ton declined from $1.72 to $1.30. Sales for rough construction were less than half as great as in 1941; but rubble sales, which were insignificant in 1941, increased greatly. Basalt is not important as a building stone, and demands for it fluctuate greatly from year to year. Some of these dark rocks are used for memorials, but such stones are classed commercially as black granites and are therefore included with the figures for monumental granite.

MARBLE

Sales of marble blocks in 1942 declined 30 percent in quantity and 21 percent in value compared with 1941. Trends in marble sales were similar to those in granite, in that building marble suffered serious declines, but sales of monumental marble were sustained almost at 1941 levels. Munition factories, barracks, and defense housing—the types of buildings that dominated the construction field in 1942—do not have marble halls. The unit value of finished monumental marble made a decisive gain. Georgia sales were maintained at a level comparable with that of 1941, but this condition was exceptional.

[3] Average value per cubic foot.

LIMESTONE

Limestone in block form is used almost exclusively for building purposes. Small quantities are employed for flagging, but employment for memorials is negligible. Limestone is used more extensively than any other type of building stone, and Indiana producers supplied about 75 percent of the rough architectural and finished (sawed and cut) limestone sold in 1942. Dimension limestone sold in 1942 was 43 percent less both in quantity and value than in 1941. This drastic decline is due to the fact that limestone sales depend almost exclusively on erection volume of the higher types of buildings, such as stores, churches, schools, post offices, courthouses, libraries, office buildings, and other similar edifices, the construction of which was virtually at a standstill in 1942. Unit prices of the various classes of limestone fluctuated considerably. Rough construction stone declined from $3.46 to $2.17 a ton, whereas cut stone, slabs, and mill blocks increased from 76 to 84 cents a cubic foot.

SANDSTONE

Sales of sandstone increased 27 percent in quantity, but their value was 22 percent less than in 1941. The gains in quantity sold were all of relatively low-priced rough construction stone and rubble, hence the low sales value. Sales of cut stone, slabs, and mill blocks declined 48 percent, but the value per cubic foot increased from $1.17 to $1.48. Curbing and flagging sales were far below those of 1941. The sandstone paving-block industry has almost disappeared. The number of active sandstone plants declined from 93 to 82.

Ohio is the leading producer, its quarries supplying 44 percent of the total value of output in 1942. The largest quarries are in the Amherst area in the northern part of the State. New York, Pennsylvania, Tennessee, and Massachusetts follow in order of sales value. The thin-bedded ornate sandstones of the Crab Orchard area, Cumberland County, Tenn., have attracted considerable attention during recent years.

The second table following presents a 20-year history of the bluestone industry. This type of sandstone, which has remarkable splitting properties, is used as a building stone and for curbing and flagging. Sales in 1942 were down 35 percent in quantity and 34 percent in value compared with 1941.

[1] New York and Pennsylvania are the only States that produce bluestone.

MISCELLANEOUS STONE

The following table gives data on certain types of dimension stone not included in the major groups already discussed. The principal varieties are mica schist, argillite, various light-color volcanic rocks, soapstone, and greenstone. The quantity sold in 1942 decreased 23 percent and the value 8 percent compared with 1941.

Miscellaneous varieties of stone (dimension stone) sold or used by producers in the United States in 1942, by States and uses

[1] Included under "Undistributed."
[2] Building stone (rough and dressed), approximately 536,450 cubic feet; flagging, approximately 20,140 cubic feet.

TRENDS IN USE OF DIMENSION STONE

Figure 1 shows graphically the history of production of dimension stone, by kinds, for a 27-year period. Dimension stone includes all classes of building stone, as well as memorial stone, paving blocks, curbing, and flagging. Limestone and granite are the leading varieties. All types of stone follow closely the general trends of national peacetime prosperity.

Figure 2 traces the history of production of all building stones and of the principal variety—limestone—in their relation to nonresidential building, the class of construction using stone most extensively. Stone is a dignified, substantial, and enduring building material that

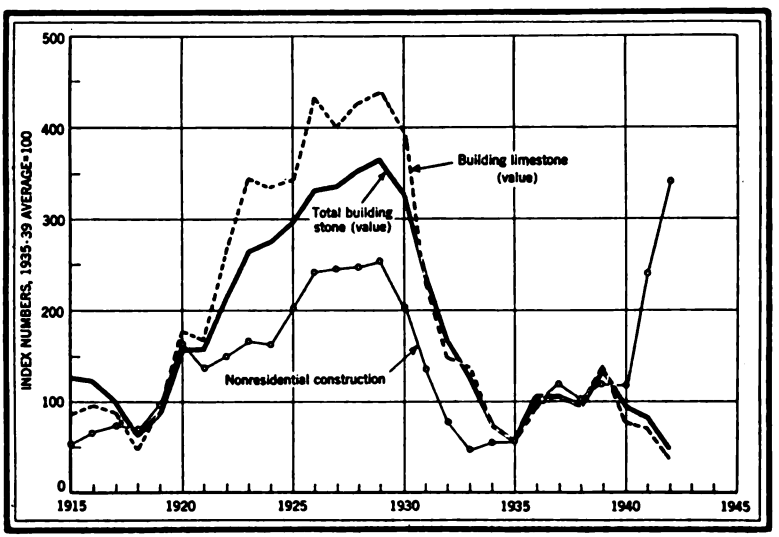

FIGURE 2.—Sales of all building stone and building limestone compared with nonresidential construction (public and private), 1915-42. Data on nonresidential building construction from Bureau of Foreign and Domestic Commerce.

Digitized by Google

is used chiefly in permanent and relatively costly structures. Wars discourage the use of dimension stone. Although military needs demand enormous expansion of factory and housing facilities, natural stone finds little or no place in such types of construction. Similarly, Nation-wide depressions have sudden and serious effects on construction, upon which the prosperity of the building-stone industries depends. As indicated in figure 2, building limestone enjoyed an 8-year period of prosperity (1923–30) after the First World War. The industry sank to low levels during the depression and was just emerging from this dark period with the prospect of another era of wider sales when the Second World War wiped out the moderate gains of 1936 to 1939 and depressed the level of activity to a point lower than that of 1918.

NEW DEVELOPMENTS

Dimension stone occupies a rather subordinate position in the war program, and no new developments in use or in technique of manufacture are to be recorded. Stone-working activities have fallen to low levels, and at the same time an unprecedented demand has arisen for men and machines to make war equipment. This condition has influenced the versatile stone industry to accommodate its facilities and manpower to the more urgent needs. Producers of monumental granite near Barre, Vt., have established a War Work Division having machine shops adapted to manufacture of munitions. The marble industry centered near Proctor, Vt., and the granite industry at Cold Springs, Minn., have likewise diverted their machinery, power, and skilled personnel to making metal parts of war equipment. Many granite workers along the coast of Maine, skilled in woodcraft of the northern forests, heeded the call in 1942 for more ships and devoted their energies to making wooden barges. It is probable that other companies are engaged in similar activities of which we have no record.

Efforts were also made to expand the manufacture of useful by-products. One Barre (Vt.) memorial stone company makes chicken grit from waste granite, thus aiding the expanding food program and simplifying the transportation of grit to New England poultry centers.

CRUSHED AND BROKEN STONE

Over 194,000,000 short tons of crushed and broken stone were sold in 1942, exclusive of that used for making cement and lime. Sales increased 7 percent in quantity and 8 percent in value compared with 1941. The average value at point of origin increased 1 cent a ton.

The following table of salient statistics shows the quantity and value of crushed and broken stone sold during 1941 and 1942 by uses. Detailed data on asphaltic stone and slate granules and flour are given in the chapters on Asphalt and Slate.

COMMERCIAL AND NONCOMMERCIAL OPERATIONS

The following table shows the production of crushed stone for concrete and road metal and railroad ballast during recent years by Government agencies of various kinds contrasted with that by commercial enterprises. Production by commercial companies increased 27 percent in 1942 compared with 1941, whereas production by Government agencies declined 55 percent. Eighty-eight percent of the total production was made by commercial companies. The large decline in noncommercial output reflects the curtailment of make-work enterprises established to combat the depression.

Concrete and road metal and railroad ballast sold or used by commercial and noncommercial operators in the United States, 1938–42

[Figures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers]

Year	Commercial operations				Noncommercial operations				Total	
	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Percent of change in quantity from preceding year
1938	60,254,170	$0.88	−3.3	63.6	34,508,880	$1.04	+32.1	36.4	94,763,050	+7.2
1939	59,516,270	.86	−1.2	57.3	44,374,750	.97	+28.6	42.7	103,891,020	+9.6

SIZE OF PLANTS

Presented herein for the first time is an analysis of production by size of plant. The determinations are based upon 1941 figures. The largest group of plants, comprising 46 percent of the total, includes those ranging in output from 1,000 to 25,000 tons a year. The second-largest group includes plants that produce 25,000 to 50,000 tons a year. These two groups, although comprising 61 percent of the total number of plants, produce less than 12 percent of the total output. The third group in importance, based upon the number of plants, includes those producing 100,000 to 200,000 tons a year; this group is second in importance in production, for it contributes 15 percent of total output. Plants producing 900,000 tons and over a year, although only 19 in number, furnish more than 23 percent of the total production. The accompanying table gives details of production by size groups.

Total	1,737	143,037,900	100.00	143,037,900

[1] Exclusive of marble, which is primarily a dimension-stone industry.

METHODS OF TRANSPORTATION

The following table shows the quantities of concrete and road metal conveyed during 1941 and 1942 by each of the principal methods of transportation. The general trend in mode of transport for the past 10 years has been toward wider use of trucks at the expense of railroads. In 1942, for the first time, this trend was reversed, and truck haulage declined from 65 percent of the total commercial output in 1941 to only 55 percent in 1942; conversely, rail tonnage increased from 24 to 30 percent of the total. This condition doubtless reflects the restrictions in use of rubber and gasoline prevalent in 1942.

Concrete and road metal sold or used by commercial producers in the United States, 1941–42, by methods of transportation [1]

Method of transportation	1941		1942	
	Short tons	Percent of total	Short tons	Percent of total
Truck	49,107,430	65.0	50,830,270	55.1
Rail	18,047,780	23.9	27,932,080	30.3
Waterway	4,690,770	6.2	4,311,930	4.7
Unspecified	3,742,840	4.9	9,177,650	9.9
	75,588,820	100.0	92,251,930	100.0

[1] For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, crushed stone for concrete and road metal moved as follows—1941: Truck 76 percent, rail 16 percent, waterway 4 percent, and unspecified 4 percent; 1942: Truck 62 percent, rail 26 percent, water 4 percent, and unspecified 8 percent.

[1] Includes stone used for artificial stone, fertilizer filler, poultry grit, spalls, stone sand, and terrazzo.

[2] Included under "Undistributed."

Digitized by Google

Sales of crushed and broken granite were about the same in 1942 as in 1941, but the value was 4 percent greater owing to an increase in sales value from $1.05 to $1.09 a ton. Production of riprap was unusually high, but on the other hand sales of concrete aggregate and stone for highway construction dropped about 1 million tons.

The number of individual operations supplying noncommercial crushed stone cannot be determined with any degree of accuracy from the reports submitted. Therefore, in the accompanying tables covering granite and other kinds of crushed and broken stone, the number of active plants is not given. For many years before 1939, when noncommercial production had less importance, such figures appeared in the tables.

BASALT AND RELATED ROCKS (TRAP ROCK)

The dark igneous rocks, basalt, gabbro, and diorite, known commercially as trap rock, are used widely for highway construction and concrete aggregate. Sales of crushed and broken trap rock were 2 percent less in 1942 than in 1941, and the value was 13 percent higher. The value per ton increased from $1.04 to $1.19.

Sales of riprap, which had declined in 1941, gained 57 percent in 1942. Stone for concrete aggregate and road metal declined moderately, but railroad-ballast sales increased substantially. The latter condition reflected the increasing care devoted to roadbeds at a time when rail traffic was exceptionally heavy.

MARBLE

Waste material from most marble quarries and mills in the United States consists of relatively pure calcium carbonate and therefore is interchangeable with high-calcium limestone for various uses. As many blocks quarried are structurally defective and as a considerable share of the good blocks is cut away in marble dressing, large quantities of waste material accumulate. Marble producers are active, therefore, in seeking profitable outlets for such waste. Some of them manufacture finely pulverized, relatively high-priced products, such as whiting and fillers. Others prepare it for terrazzo, stucco, or agricultural limestone. The rough blocks may be sold for riprap or may be crushed for use as roadstone or concrete aggregate. This diversity in preparation and use explains the great variation in price obtained in different States as indicated in the accompanying table.

Marble (crushed and broken stone) sold by producers in the United States in 1942, by States [1]

State	Active plants	Short tons	Value	State	Active plants	Short tons	Value
Alabama	2	(2)	(2)	Texas	2	6,150	$41,392

LIMESTONE

Limestone occurs in every State, and sales were reported to the Bureau of Mines from 44 of them. Because of its wide occurrence it is, in many areas, the most convenient kind of stone for highway or building construction and railroad ballast. The over-all cost of quarrying and crushing limestone is generally lower than that of the harder rocks. Limestone is an essential raw material for many metallurgical, chemical, and processing industries for which no other kinds of stone can be substituted. As a result of these various favorable conditions, limestone is by far the most widely used type of stone in the United States. In 1942 limestone constituted 73 percent of all crushed and broken stone sold (excluding that used for making cement and lime).

Sales in 1942 were 7 percent higher in quantity and 10 percent in value than in 1941. Riprap sales made small gains, and the value per ton increased from 95 cents to $1.09. Fluxing-stone sales, which reached an all-time high of more than 30 million tons, reflect the unprecedented iron-furnace activity in 1942. There was no substantial change in limestone sold for concrete aggregate and road building, but the increase in railroad-ballast sales was comparable with that of basalt and for the same reason. The 15-percent increase in sales of agricultural limestone relates directly to the stimulation of crop growing that characterized 1942.

Other uses [2]	156,250	287,933	213,980	317,478
Use unspecified	159,980	252,972	91,230	245,279
	12,303,830	13,788,732	13,199,900	14,919,089

[1] Includes stone for filler for calcimine, caulking compounds, chewing gum, cosmetics, explosives, flavoring extracts, imitation leather, linoleum, paint, paper, parting compounds, phonograph records, plastics, pottery, printing ink, putty, regrinding, roofing, rubber, sealing wax, tile, tooth powder, wire, and unspecified uses.

[2] Includes stone for acid neutralization, carbon dioxide, ceramics, chemicals (unspecified), concrete blocks and pipes, dye, foundry facings, motion-picture snow, oil-well drilling, rayon, rice milling, spalls, and spray.

Dolomite (calcium-magnesium carbonate), which occurs extensively in the United States, is attaining increasing commercial importance. Its new use as a source of magnesium metal, plus growing demands for refractory magnesia, one of its derivatives, led the Bureau of Mines to make a comprehensive survey of United States resources of this important rock.[1] Data on high-grade dolomite deposits assembled from all available published sources were supplemented by additional information secured from State geological surveys, geologists, and mining engineers. This report covers the occurrences by geographic areas and by States. The extent and thickness of the deposits, altitude of beds, accessibility, workability, and composition are described. An important feature of the paper is a series of tables comprising about 1,000 representative analyses of dolomites from all parts of the country. A map shows the location of the deposits.

The record-breaking demand for refractories to maintain maximum operation of innumerable furnaces turning out metal for war munitions resulted in so many calls for information on special types of heat-resisting products that the Bureau prepared a report [2] dealing with all recent developments in the refractories for which dolomite is used as raw material.

Sales of dolomite and its primary product of calcination—dolomitic lime—for certain special uses are covered in the following table:

[1] Weitz, John H., High-Grade Dolomite Deposits of the United States: Bureau of Mines Inf. Circ. 7226, 1942, 86 pp.

[2] Schallis, Alvin, Dolomite-Base Refractories: Bureau of Mines Inf. Circ. 7227, 1942, 11 pp.

Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1941–42

	1941	1942
Dolomite for—		
Basic magnesium carbonate:		
Short tons	105,670	117,650
Value	$136,180	$151,756
Dead-burned dolomite or refractory stone:		
Short tons	980,190	1,354,090
Value	$729,792	$1,197,386
Dolomitic lime for—		
Refractory (dead-burned dolomite):		
Short tons	1,069,887	1,229,357
Value	$9,111,172	$10,817,634
Paper mills:		
Short tons	78,000	85,000
Value	$551,000	$604,000
Total (calculated as raw stone)—short tons	3,382,000	4,100,000

Fluxing limestone has attained such importance that the Bureau of Mines for the first time has separated the figures by principal uses, as indicated in the accompanying table.

Sales of fluxing limestone, 1938–42, by uses

Year	Blast furnaces		Open-hearth plants		Other smelters [1]		Other metallurgical [2]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1938	6,449,520	$4,455,693	2,459,820	$1,919,097	721,930	$502,642	60,860	$56,189	9,692,130	$6,933,621
1939	13,115,580	9,505,807	3,471,570	2,638,935	522,330	331,969	162,080	142,227	17,271,560	12,618,938
1940	15,611,720	10,638,341	6,500,680	4,462,852	342,240	278,726	402,270	358,968	22,856,910	15,738,887
1941	20,244,510	14,832,938	6,332,210	4,469,838	481,100	398,839	374,700	362,544	27,432,520	20,064,159

[1] Includes flux for copper, gold, lead, zinc, and unspecified smelters.
[2] Includes flux for foundries and for cupola and electric furnaces.

Limestone is quarried not only for use raw but also for manufacture into cement and lime. The large and important industries manufacturing these products are covered in separate chapters of the Yearbook. It is of interest, however, to show in one table, as follows, the total tonnage of limestone consumed for all purposes.

Limestone sold or used for all purposes in the United States, 1940–42, in short tons

Use	1940	1941	1942
Limestone (as given in this report) (approximate)	112,658,000	133,164,000	142,488,000
Portland cement (including "cement rock") [1]	34,041,000	42,735,000	47,657,000
Natural cement ("cement rock") [1]			
Lime [2]	9,774,000	12,159,000	12,208,000
	156,473,000	188,058,000	202,353,000

[1] Reported in terms of cement in chapter on Cement.
[2] Reported in terms of lime in chapter on Lime.

SANDSTONE

Sales of crushed sandstone were 13 percent lower in quantity and 20 percent lower in value in 1942 than in 1941. Ganister, the principal raw material of silica brick used extensively to line open-hearth steel furnaces, was produced in larger quantities in 1942 than in any previous year. The output was 2 percent greater than the former high of 1917.

[1] Includes sandstone for chemical use, fill material, filter stone, poultry grit, road base, rock wool, roofing granules, and stone sand. [2] Included under "Undistributed."

MISCELLANEOUS STONE

Crushed and broken stone, other than the five principal varieties already discussed, includes light-color volcanic rocks, schists, boulders from river beds, serpentine, and flint. The following table shows sales of stone of these types, by States and uses, in 1942; such sales increased 50 percent in quantity and 8 percent in value over 1941.

Digitized by Google

MARKETS

As crushed stone is an important building material, sales generally are related closely to the volume of building construction. One of its leading uses is as aggregate in concrete, therefore sales should normally follow the trends of cement shipments and the area of concrete pavements that are constructed. These relationships are indicated in figure 3. Concrete aggregate failed to pace the enormous increase in total building because concrete was employed less extensively in the temporary or semipermanent types of structures erected in 1942 than in normal peacetime structures.

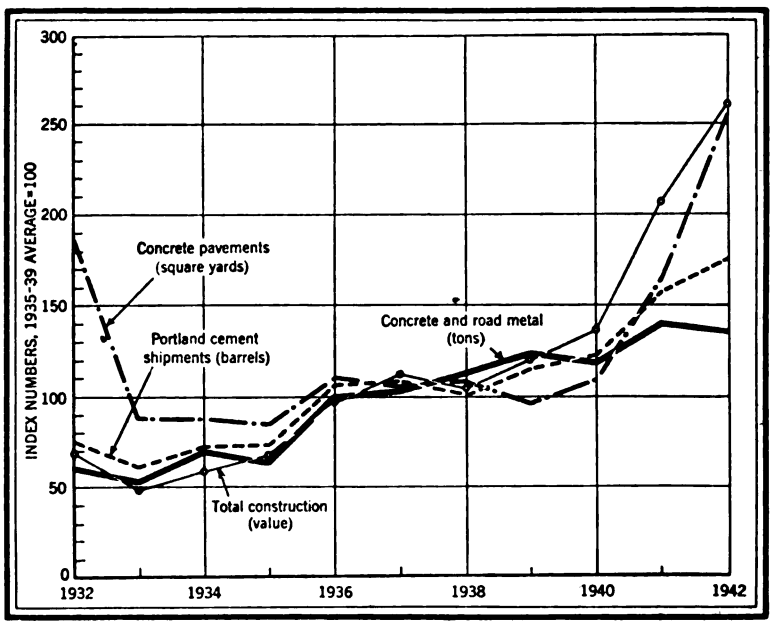

FIGURE 3.—Crushed-stone aggregates (concrete and road metal) sold or used in the United States compared with shipments of portland cement, total construction (value), and concrete pavements (contract awards, thousands of square yards), 1932–42. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

Pig-iron production, which reached more than 59 million tons in 1942, surpassed all previous records, and therefore the demands for limestone furnace flux were unprecedented. To produce more than 86 million tons of steel, mills were forced to capacity. To replace burned-out furnace linings and to keep them in repair placed an unusual burden on producers of dolomite for refractory use and of ganister for manufacture of silica brick. The relations of fluxing-stone output to pig-iron production and of refractory stone to steel-ingot manufacture over an 11-year period are indicated in figure 4. The demand for refractory stone in excess of normal requirements of the iron and steel industries, as indicated in this figure, probably was due to the shorter life of furnace linings under the stress of forced output.

Digitized by Google

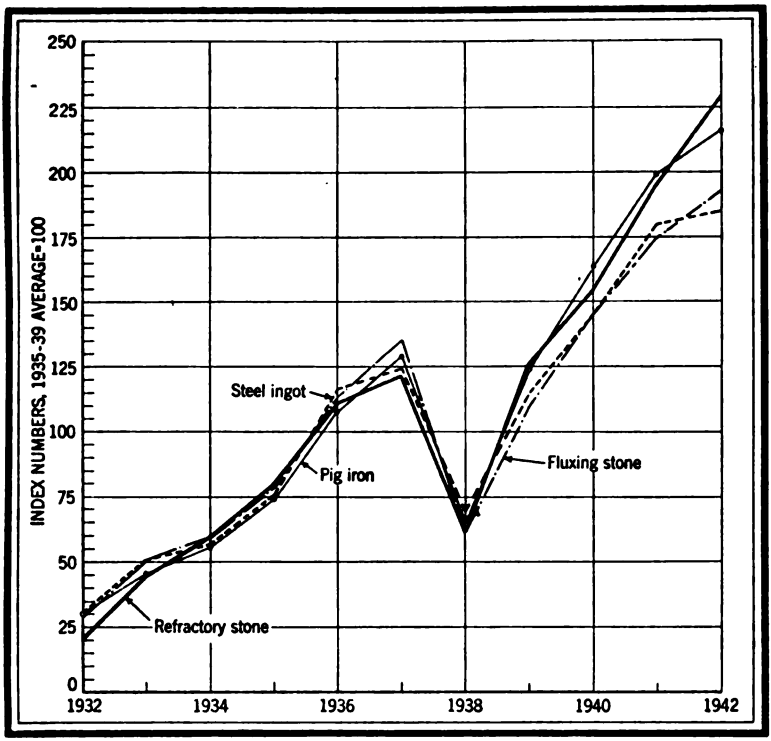

FIGURE 4.—Sales (tons) of fluxing stone and refractory stone including that used in making lime as recorded in the chapter on Lime compared with production of steel ingot and pig iron, 1932–42. Statistics of steel-ingot production compiled by American Iron and Steel Institute.

NEW DEVELOPMENTS

Little is to be reported for 1943 on new plant construction or plant rehabilitation because necessity had to be shown and priorities obtained for all new equipment. Some increased facilities were authorized where the quarry output was used in military projects. Quarry operators had difficulty at times in obtaining necessary supplies and repairs, and their ingenuity and inventiveness were exercised in devising ways and means of coping with equipment difficulties. Used equipment was accommodated to replacement needs in some instances.

A good example of ways in which valuable materials are conserved is a method devised for reusing drill steel that ordinarily would be unserviceable. High-carbon drill steel is in heavy demand, and to maintain maximum supplies short lengths and broken quarry drills are now reclaimed by joining them into long drills. This is accomplished by skillful oxyacetylene welding.

FOREIGN TRADE

Exports and imports of stone are relatively small. Figures for a recent 5-year period are shown in the accompanying table. Average exports for the 3-year period, 1938 to 1940, for which figures are comparable, were only 0.1 percent of average domestic sales during the same period. Average imports for the 4 years, 1937 to 1940,

Digitized by Google

were only 0.5 percent of average domestic sales for that period. Owing to wartime restrictions, no figures on foreign trade can be published, but it is apparent from the data on foreign movement of stone recorded herein that their absence for 1942 will not detract appreciably from the value of the report, particularly in view of the recent rigid restrictions on foreign movement of commodities deemed unessential to the war program. Foreign trade figures will be released at the termination of the present war emergency to preserve the continuity of the statistical record.

Value of United States exports and imports of stone, 1937–41

Year	Exports	Imports					
	Marble and other building and monumental stone	Marble	Granite	Quartzite	Travertine	Other	Total
1937	[1] $88,528	$435,361	$245,819	$249,003	$18,677	$32,566	$981,426

[1] Marble only.
[2] January to September, inclusive.

Exports.—Marble is the principal variety of stone exported. Normally over 90 percent of the exports are shipped to Canada and the remainder chiefly to Cuba, Newfoundland, Mexico, and various Central and South American countries. Before the war small quantities were shipped to Germany, the United Kingdom, and other parts of Europe.

Imports.—Before the war Italy, France, Belgium, and Spain were the chief sources of foreign marbles. Mexico and Argentina are the principal suppliers of onyx marbles.

Moderate quantities of granite are imported from Canada, and when shipping was unrestricted Finland and Sweden were the most important sources outside of the American continent. Red granite from Finland is popular for polished monumental work, and gabbro (black granite) from Sweden finds a ready market, particularly in the New York area. Other European countries have furnished limited quantities.

Quartzite imports originate in Canada and are used principally for the manufacture of ferrosilicon. Travertine has been obtained almost exclusively from Italy. Before 1940 it was an important foreign building material that was popular thoughout the United States for floor tile, steps, and wainscoting.

SLATE

By Oliver Bowles and M. S. Jensen

SUMMARY OUTLINE

	Page		Page
Summary	1255	Prices	1259
Salient statistics	1256	Price history	1259
Sales	1257	Review by States and districts	1260
Dimension slate	1257	New developments	1262
Granules and flour	1258	Foreign trade	1263

SUMMARY

Sales of slate as dimension stone were 41 percent lower in quantity and 33 percent lower in value in 1942 than in 1941. This drastic decline may be attributed chiefly to rigid curtailment of private residential building and small demand for slate in the types of defense-housing units that were constructed in 1942. Very few homes of the type that commonly have slate roofs were erected during the year. Unit prices were in general higher than in 1941.

Roofing-slate sales were little more than half as great as in 1941, in quantity or value; the average value per square in 1942 was $8.87, whereas in 1941 it was $8.39. Sales in the Pennsylvania area were 49 percent lower, in both quantity and value, than in 1941. In the New York-Vermont area, sales declined 49 percent in quantity and 39 percent in value. Virginia sales dropped 49 percent in quantity and 48 percent in value.

Sales of mill stock declined only about 1 percent in quantity but gained 3 percent in value. Sales of electrical slate, which made phenomenal gains in 1941, made a further advance of 10 percent in quantity and 14 percent in value in 1942, attaining the highest level of production since 1930. These gains during the past 2 years undoubtedly reflect the great increase in utilization of electric power in connection with the enormous growth in manufacture of war munitions. Although total new construction increased from 208 percent of the 1935–39 average in 1941 to 261 percent in 1942, sales of structural and sanitary slate declined 1 percent in quantity; they gained 3 percent in value. It is evident that the types of military building that predominated in the construction field in 1942 require less slate than peace-time building. Sales of vaults and covers increased 2 percent in quantity and value.

A decline of only 6 percent in quantity and 10 percent in value of blackboards and bulletin boards, even though school and college construction was almost negligible, indicates that blackboards found considerable use in military instruction centers. A decline of 31 percent, in both quantity and value, in sales of billiard-table tops indicates that they are not essential from a military standpoint. Sales of

Digitized by Google

school slates increased 8 percent in quantity and 15 percent in value. Sales of flagstones and stepping stones were lower than in 1941.

Statistics on slate granules and flour are included in this chapter, although these products have little connection with the dimension-slate industry, except that granules are used in roofing products that compete in the roofing-slate market. For the most part, slate used for the manufacture of granules is unsuitable for other slate products. Sales of granules increased 10 percent in quantity and 9 percent in value and sales of flour 12 percent in quantity and 13 percent in value compared with 1941. Granules are used chiefly in the manufacture of low-cost roofing, and their wide employment was to satisfy the demands of military camps, warehouses, and other more or less temporary structures built for military needs. In 1942, the average sales value of granules f. o. b. mill was $8.29 and of flour $3.53 per short ton, compared with $8.37 and $3.49, respectively, in 1941. Figures for sales of granules made of rock other than slate are given in the chapter of this volume on Stone.

The following table, presenting the principal statistical data for the slate industry during 1941 and 1942, is arranged to permit ready comparison of the 2 years.

Salient statistics of the slate industry in the United States, 1941–42

SALES

Dimension slate.—All slate products except granules and flour are classed as dimension slate because they consist of blocks or slabs cut to specified sizes and shapes. The following table shows sales of such products for a 5-year period.

Slate (other than granules and flour) sold by producers in the United States, 1938–42

Year	Roofing			Mill stock		Other [1]		Total	
	Squares	Approximate equivalent short tons	Value	Approximate short tons	Value	Approximate short tons	Value	Approximate short tons	Value
1938	322,040	119,590	$2,247,910	16,310	$853,602	7,790	$63,839	143,690	$3,165,351
1939	399,320	149,410	2,868,961	21,710	1,168,671	8,480	63,493	179,600	4,101,125
1940	347,130	127,600	2,436,123	17,070	935,810	9,780	64,435	154,450	3,436,368

1942	192,070	71,400	1,704,053	18,720	1,112,426	16,910	139,328	107,030	2,955,807

[1] Includes flagstones, walkways, stepping stones, and miscellaneous slate.

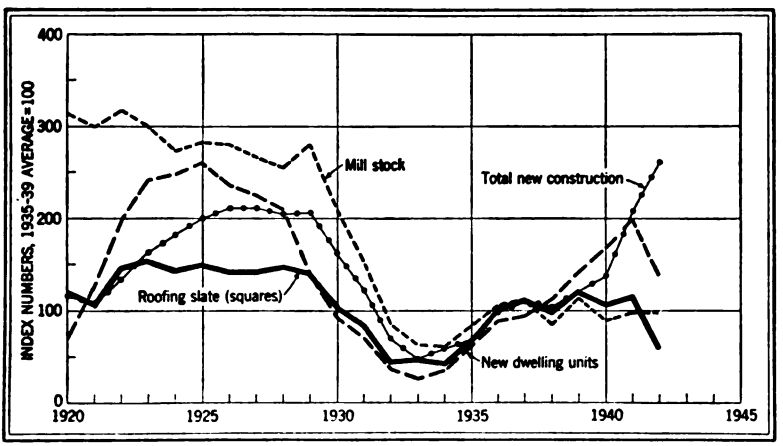

FIGURE 1.—Sales of roofing slate and mill stock compared with new dwelling units and total new construction, 1920–42. Data on new construction from Bureau of Foreign and Domestic Commerce and on new dwelling units from Bureau of Labor Statistics.

Figure 1 compares sales of roofing slate and mill stock with the number of new dwelling units and total new construction from 1920 to 1942. Roofing slate, which is used chiefly in residential construction, failed to keep pace with new dwelling units from 1921 to 1929. From that date until 1938, residential building was at a low ebb, with roofing-slate sales showing small proportional gains. From 1939 to 1941, new residential building made rapid strides and slate roofing made relatively small gains. In 1942, residential construction underwent a decline comparable in severity with that of 1929; and roofing-slate sales, already at a low level, experienced a similar decline.

Mill stock is used most widely in nonresidential building. As indicated in figure 1, mill-stock sales maintained a favorable position with respect to total new construction from 1920 to 1937, but thereafter

Digitized by Google

they lagged. The demand for mill stock failed to respond to the upsurge of total construction in 1941 and 1942 because the predominant military construction consisted largely of temporary structures, in which little or no slate was used.

Figure 2 presents graphically a statistical history of slate by uses over a 28-year period. All branches of the industry experienced a serious decline during the depression years, and although some recovery took place in subsequent years the upturn was reversed in 1942 because dimension slate is used very little in military building. Slate-granule sales, however, have expanded, because slate-surfaced composition roofing is in wide demand for temporary and semipermanent building.

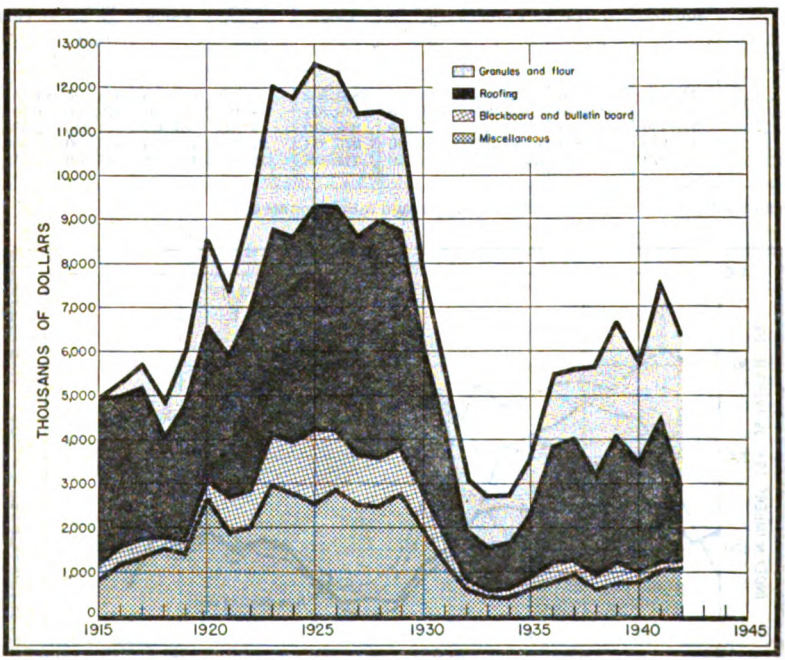

FIGURE 2.—Value of slate sold in the United States, 1915–42, by uses.

Figure 3 presents the same history as figure 2, except that quantities rather than values are used. Products of low unit value naturally assume greater prominence in this chart, whereas the higher-priced products, such as blackboards, become relatively insignificant on a quantity basis.

Granules and flour.—Slate granules are used extensively in surfacing prepared roofing; and slate flour is employed as a filler in paints, road asphalt-surface mixtures, roofing mastic, oilcloth, linoleum, and various other products. The use of these commodities showed substantial gains in 1942 because of their application to military needs.

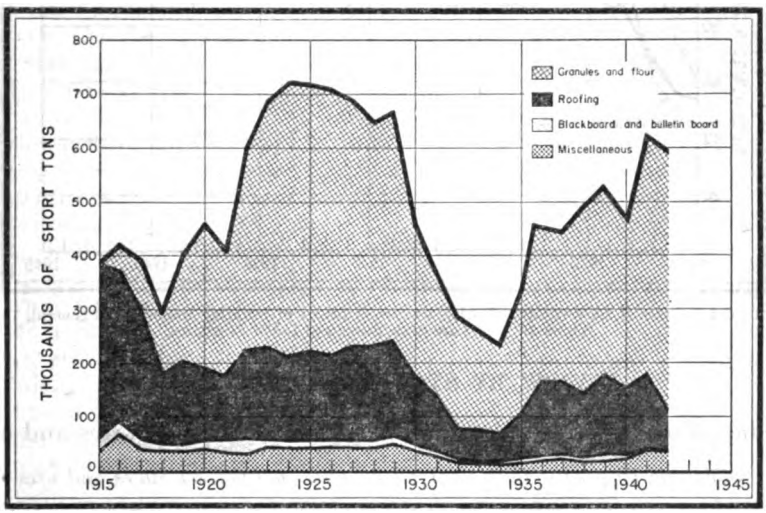

FIGURE 3.—Quantity of slate sold in the United States, 1915–42, by uses.

PRICES

The average price of roofing slate f. o. b. quarry or mill, as reported to the Bureau of Mines, increased 48 cents a square in 1942 compared with 1941. In Pennsylvania it increased 14 cents, in the New York-Vermont area $1.57, and in Virginia 23 cents a square.

The price of mill stock increased from 33 cents a square foot in 1941 to 35 cents in 1942. Average values of electrical and structural and sanitary slate increased 2 cents a square foot; those for vaults and covers and billiard-table tops remained unchanged; those for blackboards and bulletin boards decreased 1 cent a square foot; and those for granules and flour decreased 6 cents a short ton.

Price history.—Figure 4 shows the trend in slate prices compared with building materials in general over a 28-year period. Slate prices were lower than those of building materials in general from 1915 to 1920, but from that time until 1932 prices of both roofing and mill stock were well above the average of all building materials. Since 1932 slate prices have varied only moderately from the general average.

Digitized by Google

Maine.—Slate produced in Maine is used chiefly for electrical panels, for which it possesses superior qualities. Sales of this product increased 16 percent in quantity and 14 percent in value compared with 1941. Sales of roofing slate were approximately only one-third as large in quantity and value as in 1941; such slate, however, is a small fraction of the Maine slate industry.

New York-Vermont.—Continuing the decline in roofing-slate sales recorded for the 2 preceding years, sales in 1942 were little more than half as great as in 1941; the value of sales declined 39 percent. Mill-stock sales declined 44 percent in quantity and 13 percent in value; but the value of other products, chiefly granules and flour, dropped less than 1 percent. The value of all slate products sold in Vermont in 1942 was 14 percent and in New York 4 percent lower than in 1941. This slate area is the outstanding source of colored roofing slates in the United States. Their attractive green, red, purple, and mottled colors and adaptability to architectural design, combined with excellent enduring qualities, fit them especially for churches, libraries, colleges, and Government and other public buildings, as well as for moderate- and high-priced homes. It was because such types of construction were so lacking in 1942 that the roofing-slate industry of the New York-Vermont area declined so severely.

Peach Bottom district.—Blue-black slates of high quality have been quarried for more than 200 years on the Maryland-Pennsylvania border near Delta, Pa. Many years ago several companies produced roofing slate in this area, but all ceased operation because of drainage difficulties and costly slides of overburden and debris. In 1937 a new roofing-slate operation was developed in Pennsylvania, and it has become a substantial producer. Granules and slate flour are manufactured in both States.

Lehigh district.—The most productive slate area in the United States is in Lehigh and Northampton Counties, Pa.; all kinds of slate products are manufactured. As separate figures cannot be shown for York County, Pa., it is included with Northampton County in the accompanying table.

The value of total sales of slate products in the Lehigh district was 25 percent lower in 1942 than in 1941. Sales of roofing slate were 49 percent less in both quantity and value. The following mill-stock products gained in both quantity and value: Structural and sanitary slate (8 percent in quantity and 18 percent in value), vaults and covers (2 percent in both quantity and value), and school slates (7 percent in quantity and 15 percent in value); the following declined in both quantity and value: Electrical slate (26 percent in quantity and 28 percent in value), blackboards and bulletin boards (6 percent in quantity and 10 percent in value), and billiard-table tops (30 percent in quantity and 29 percent in value). Other products, chiefly granules and flour, gained 20 percent in value compared with 1941.

NEW DEVELOPMENTS

The possibilities of using waste slate as a source of lightweight aggregates have been studied by the Bureau of Mines, and the results appear in a recent publication.[1] Slates from Pennsylvania, Maine, and Maryland gave a satisfactory degree of bloating upon calcination. Concretes made with the resulting aggregates weighed 103 to 107 pounds per cubic foot, whereas concretes made with standard crushed-stone or gravel aggregates weigh about 142 pounds per cubic foot. Concrete made with expanded slate aggregates was found to possess adequate strength for general structural uses. Such lightweight concretes can be used advantageously for bridge decks, arches, floors, and walls where the structural design demands a minimum dead load. As enormous quantities of waste accumulate in all slate-producing centers, the development of such a byproduct industry is highly desirable.

The results of a survey of roofing materials in the South Central States, recently published by the National Bureau of Standards,[2] bring out the interesting fact that slate covered only 0.75 percent of all the roofs examined. In view of the fact that one of the major roofing slate-producing regions of the United States—Buckingham

[1] Conley, John E., Waste Slate as a Raw-Material Source of Lightweight Aggregates: Trans. Am. Inst. Min. and Met. Eng., vol. 148, Industrial Minerals (Nonmetallics), 1942, pp. 161-166.

Digitized by Google

County, Va.—is within easy reach of the northern part of the area covered in the survey, it is remarkable that slate, which possesses superior durability and attractive appearance, should have been used so sparingly. The potential market for roofing slate is enormous, but the industry has made little progress in developing the market.

Considerable publicity has been given to a patent process of laying roofing slate with a single lap over heavily coated asphalt roofing. Each slate is held in place with a single nail and a metal clip. The advantages claimed are a reduction of nearly 50 percent in the quantity of slate needed, weight of roof, and cost, compared with roofs laid according to the American method. At the same time, the roof is said to equal the ordinary slate roof in appearance and durability. Wide acceptance of this new method by architects and builders would tend greatly to increase the use of roofing slate, particularly in the field of low-cost housing where slate is commonly regarded as too costly for extensive use.

FOREIGN TRADE

Owing to wartime restrictions no figures on foreign trade can be published; they are, however, of so little significance in the slate industry that their absence will not detract appreciably from the value of this report.

The total annual value of imports for the 10-year period 1932 to 1941 ranged from a high of $17,317 in 1932 to a low of $520 in 1940 and averaged about $7,000 a year. This is only about 0.2 percent of the average annual domestic sales for the period. These small imports originated in various countries, chiefly Italy, Poland, Netherlands, Czechoslovakia, and United Kingdom.

Exports of slate products (exclusive of granules and flour), as reported by producers, are higher than imports. From 1932 to 1941 their value ranged from $26,042 in 1933 to $75,656 in 1940 and averaged about $55,000 a year. This is a little more than 1 percent of the average annual sales value (including granules and flour) during the period. Exports consist of roofing, school slates, electrical slates, blackboards, billiard-table tops, and various structural slate products. Canada, Mexico, and South and Central America are the principal destinations.

SAND AND GRAVEL

By G. W. Josephson and G. E. Tucker

SUMMARY OUTLINE

	Page		Page
Summary	1265	Principal trends	1275
Salient statistics	1266	Sand and gravel for construction	1275
Production	1267	Industrial sands	1275
Government-and-contractor production	1273	Employment and productivity	1276
Method of transportation	1274	Prices	1278
Degree of preparation	1274	New developments	1279
Size of plants	1275	Foreign trade	1279
		Blast-furnace slag	1280

SUMMARY

As an integral part of the great wave of wartime construction, the production of sand and gravel in 1942 exceeded 300 million tons and surpassed all previous records. The quantity and value of total production over a period of years are indicated in figure 1.

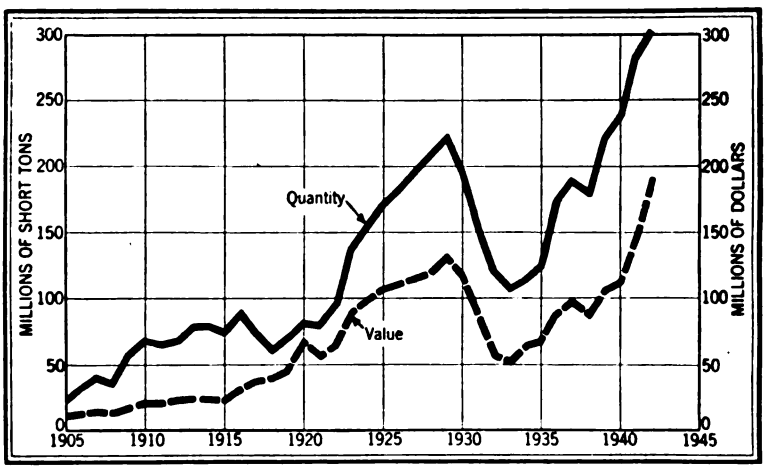

Figure 1.—Total production of sand and gravel in the United States, 1905–42.

With the increase in activity came an appreciable improvement in production efficiency and firmer prices, counterbalanced by rising operating expenses in the form of increased wage, transportation, and material costs. The War Production Board, the Office of Price Administration, and the Office of Defense Transportation greatly influenced the practices of the industry in 1942.

A noteworthy trend is visible in the fact that whereas commercial operations increased their tonnage 28 percent in 1942 compared with 1941, the output of Government-and-contractor [1] operations was 33

[1] Prior to 1939 classified as "noncommercial"; details of change in designation given in Minerals Yearbook, 1940, Review of 1939, p. 1214.

Digitized by Google

percent lower. Private building, highway construction, and many large public works projects like those of the Work Projects Administration have been curtailed or eliminated to concentrate the men, money, equipment, and materials on more critical wartime activities. Salient statistics on sand and gravel for 1941 and 1942 are summarized in the following table.

Sand and gravel sold or used by producers in the United States, 1941–42, by commercial and Government-and-contractor operations and by uses

	1941			1942			Percent of change in—

PRODUCTION

Approximately 5 percent more sand and gravel was produced in 1942 than in 1941 and for the fourth successive year a new record was attained. As stocks of sand and gravel held by producers are small in tonnage and not subject to great variation from year to year, the quantity of materials sold or used is virtually equivalent to production. Throughout this report, sales and production are used interchangeably. The following table summarizes total production of sand and gravel during the 5-year period 1938–42.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States, 1938–42

Year	Sand		Gravel (including railroad ballast)		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1938	57, 113, 828	$33, 935, 725	124, 206, 405	$51, 987, 122	181, 320, 233	$85, 922, 847
1939	72, 542, 000	41, 608, 000	153, 466, 000	64, 458, 000	226, 008, 000	106, 066, 000
1940	78, 674, 000	45, 332, 000	159, 634, 000	65, 356, 000	238, 308, 000	110, 688, 000
1941	103, 835, 000	62, 152, 000	184, 880, 000	85, 055, 000	288, 715, 000	147, 207, 000
1942	107, 371, 000	74, 443, 000	196, 975, 000	114, 057, 000	304, 346, 000	188, 500, 000

Details of production in 1942, by States and uses, are presented in the following tables. California, with the greatest tonnage ever recorded from a single State, was the leading producer, and Texas, Illinois, New York, Michigan, Ohio, and Indiana followed in the order named.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States in 1942, by States

State	Short tons	Value	State	Short tons	Value

Government-and-contractor production.—Reflecting the changing pattern of activity in the industry, Government-and-contractor production of sand and gravel in 1942 was 33 percent lower than in 1941. State governmental agencies reported 33 percent of the total, counties 26, municipalities 2, and other agencies (principally Federal organizations) 39 percent. An outstanding development was the continued decrease in direct production by governmental agencies, as indicated by the fact that contractors contributed 48 percent of the total in 1942 compared with 38 percent in 1941 and 27 percent in 1940. State agencies reported that contractors supplied them with 52 percent of their requirements in 1942.

Average value per ton of contractor tonnage increased considerably, but material produced by construction and maintenance crews was valuod only slightly higher than in 1940 and 1941. Other details are shown in the following tables.

Sand and gravel sold or used by Government-and-contractor producers in the United States, 1938–42, by uses

Year	Sand				Gravel				Total Government-and-contractor sand and gravel	
	Building		Paving		Building		Paving			
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

METHOD OF TRANSPORTATION

Despite adverse conditions, such as rubber and gasoline shortages, trucks transported the major part of all sand and gravel produced in 1942. Railroads were second in importance, handling nearly half of the output of commercial operations. Waterways furnished minor but locally important facilities.

Sand and gravel sold or used by commercial producers in the United States, 1941–42, by methods of transportation [1]

Method of transportation	1941		1942	
	Short tons	Percent of total reported	Short tons	Percent of total reported
Truck	74,452,542	44.9	103,777,190	47.4
Rail	69,225,395	41.7	93,456,656	42.7
Waterway	22,201,899	13.4	21,603,759	9.9
Total reported	165,879,836	100.0	218,837,605	100.0
Percent of total commercial production covered		91.0		94.0

[1] For practical purposes the entire output of Government-and-contractor operations commonly is moved by truck. Including Government-and-contractor production, sand and gravel moved as follows—1941: Truck 67 percent, rail 25 percent, and waterway 8 percent; 1942: Truck 60 percent, rail 32 percent, and waterway 8 percent.

DEGREE OF PREPARATION

Refinements in the technology of the various consuming industries have advanced to a point that preparation was required for 72 percent of the sand and gravel used in 1942. Part of this high percentage is due to reduced consumption in many public projects that require only bank-run material, but the proportion of prepared material has not been under 59 percent during the past 5 years. As shown in the accompanying table, most of the prepared material is supplied by commercial operations, and this largely explains the fact that the average value per ton reported by commercial producers is appreciably higher than that from Government-and-contractor operations.

Sand and gravel (prepared or unprepared) sold or used by producers in the United States, 1941–42, by commercial and Government-and-contractor operations

	1941			1942		
	Quantity		Average value per ton	Quantity		Average value per ton
	Short tons	Percent		Short tons	Percent	
Commercial operations:						
Prepared	159,784,239	88	$0.67	200,131,369	86	$0.73
Unprepared	21,772,228	12	.33	32,816,418	14	.38
	181,556,467	100	.63	232,947,787	100	.68
Government-and-contractor operations:						
Prepared	22,311,000	21	.49	20,076,000	28	.67
Unprepared	84,848,000	79	.25	51,323,000	72	.30
	107,159,000	100	.30	71,399,000	100	.41
Grand total	288,715,000		.51	304,346,000		.62

SIZE OF PLANTS

The average commercial sand and gravel plant is a comparatively small operation. Approximately half of the plants produce less than 25,000 tons per year, and the average output per plant in this group was about 8,100 tons in 1942. Only 23 percent of the producers reported more than 100,000 tons in 1942 but they supplied 78 percent of the total tonnage. Details of output, by size groups, for 1941 and 1942 are given in the following table.

Comparison of number and output of commercial sand and gravel plants in the United States, 1941–42, by size groups [1]

Size group in short tons	1941				1942			
	Plants [2]		Production		Plants [2]		Production	
	Number	Percent of total	Short tons	Percent of total	Number	Percent of total	Short tons	Percent of total
Less than 25,000	1,104	48.5	9,404,000	5.5	1,258	49.2	10,225,000	4.6
25,000 and less than 50,000	390	17.1	13,902,000	8.1	366	14.3	13,139,000	5.9
50,000 and less than 100,000	331	14.6	23,168,000	13.4	336	13.1	24,591,000	11.1

400,000 and less than 500,000	29	1.3	12,867,000	7.5	34	1.3	14,961,000	6.8
500,000 and less than 600,000	16	.7	8,880,000	5.1	24	1.0	13,046,000	5.9
600,000 and less than 700,000	8	.4	5,106,000	3.0	14	.5	8,918,000	4.0
700,000 and less than 800,000	10	.4	7,526,000	4.4	12	.5	8,972,000	4.1
800,000 and less than 900,000	5	.2	4,186,000	2.4	5	.2	4,112,000	1.9
900,000 and less than 1,000,000	4	.2	3,734,000	2.2	3	.1	2,819,000	1.3
1,000,000 and over	7	.3	12,068,000	7.0	18	.7	26,523,000	12.0
	2,274	100.0	172,473,000	100.0	2,557	100.0	221,192,000	100.0

[1] Plants operated by or for States, counties, and municipalities are not included; also not included are approximately 187 railroad plants with an output of 9,083,000 tons of sand and gravel in 1941, and 172 plants with an output of 11,756,000 tons in 1942.

[2] Includes a few companies operating more than 1 plant but not submitting separate returns for individual plants.

PRINCIPAL TRENDS

Sand and gravel for construction.—Over 90 percent of the sand and gravel marketed in the United States is absorbed by the construction industries for use in building and paving and as railroad ballast. Figure 2 shows the correlation between total construction activity, concrete-pavement contract awards, sales of sand, and sales of gravel. Production of these commodities has expanded greatly in satisfying the demands of the tremendous military and civilian construction programs of the rearmament period. During the latter part of 1942 the rate slowed down appreciably as many projects reached completion; and with the curtailment of private building, highway construction and maintenance, and public works programs, all signs point to a reduced output of sand and gravel in 1943.

Industrial sands.—Sand has many important uses in the manufacturing industries. Glass and molding sands are practically indispensable in their fields; and others, like filter, engine, and abrasive sands, perform vital functions. Except for filter and grinding and polishing sands, production of all the industrial sands was greater in 1942 than in 1941. Owing to the fact that these sands enter directly into the manufacturing and operational processes, their volume

Digitized by Google

undoubtedly will be better-maintained throughout the wartime period than will the construction sands. Figures 3 and 4 show graphically details of production of these sands in past years, and their correlation with indexes of industrial production.

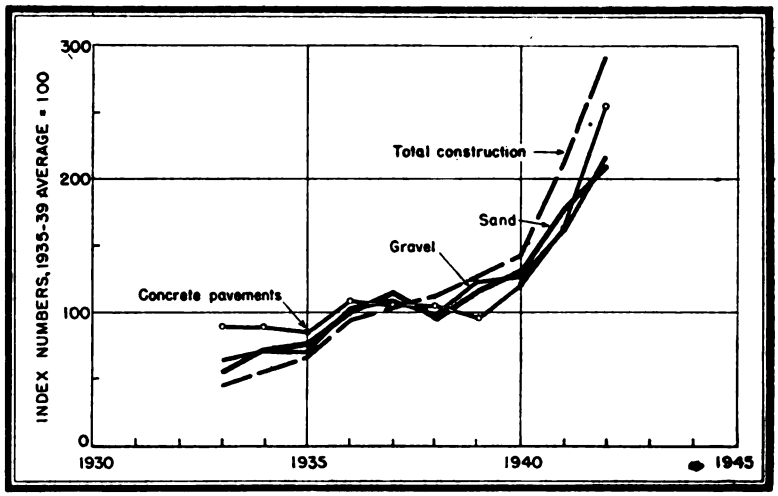

FIGURE 2.—Value of sand and gravel production compared with total construction (value) and concrete pavements (contract awards, thousands of square yards) in the United States, 1933–42. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

EMPLOYMENT AND PRODUCTIVITY

In 1941 employment in the commercial sand and gravel industry reached the highest level since the Bureau of Mines began recording manpower information in 1933.[2] Operators who produced about four-fifths of the total tonnage reported employment data for 1941, and from this information it is apparent that approximately 25,000 men were employed in the industry in that year. The number and length of the working days increased, and average output per man-hour reached a record high—12 percent above the 1940 performance.

Employment in the commercial sand and gravel industry, sand and gravel produced at plants included in the study, and average output per man in the United States, 1936–41 [1]

Year	Employment					Production			Percent of commercial industry represented
	Average number of men	Time employed		Man-hours		Commercial sand and gravel (short tons)	Average per man (short tons)		
		Average number of days	Total man-shifts	Average per man per day	Total		Per shift	Per hour	
1936	16,127	207	3,332,532	8.6	28,672,615	95,219,468	28.6	3.3	83.8
1937	16,062	215	3,458,994	8.6	29,754,746	97,113,001	28.1	3.3	81.8
1938	14,971	201	3,001,796	8.5	25,578,807	81,742,896	27.2	3.2	81.1

Digitized by Google

Productivity data for 1941, by regions, are summarized in the accompanying table. Outstanding is the fact that production efficiency improved in every district except one in which the same rate

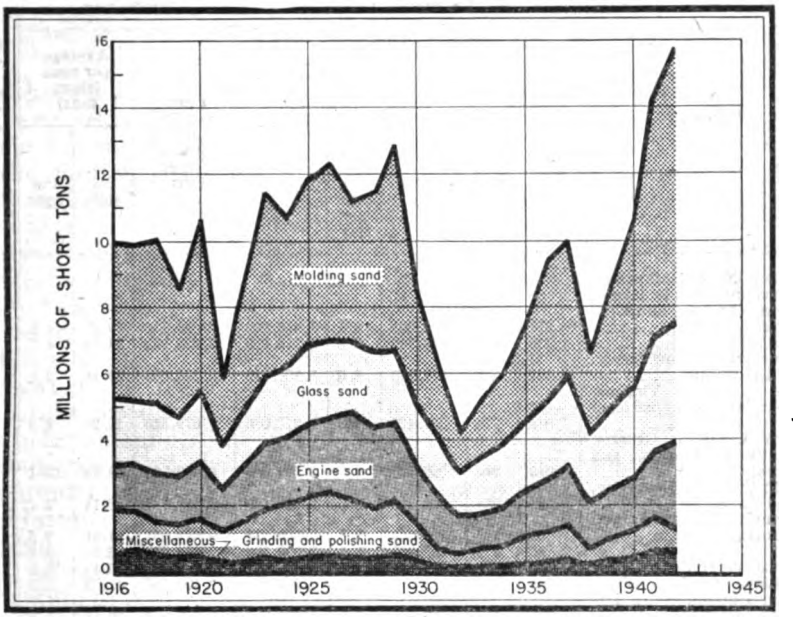

FIGURE 3.—Production of industrial sands in the United States, 1916–42.

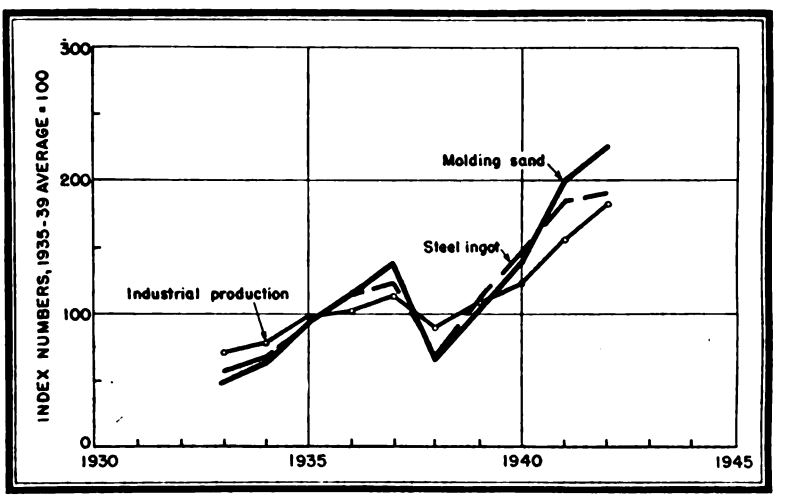

FIGURE 4.—Trends in production of molding sand compared with industrial production and output of steel ingots, 1933–42. Index of industrial production from Federal Reserve Board; statistics of steel-ingot production compiled by American Iron and Steel Institute.

was maintained as in the previous year. Many of the increases were substantial, the average being 0.4 ton per man-hour for the entire country. That this improvement represents a legitimate gain in efficiency is indicated by the fact that the degree of preparation of the material was exactly the same in both years.

[1] Excludes plants operated by or directly for States, counties, municipalities, and other Government agencies.

PRICES

The ton values of every class of sand and gravel were higher in 1942 than in 1941.

Increases in ton value averaging 54.8 percent for sand and 33.3 percent for gravel were registered for the output of Government-and-contractor operations. Smaller but substantial gains, averaging 7.6 percent for sand and 8.2 percent for gravel, were made by commercial operations. Additional statistical details covering total and ton values of the various classes of sand and gravel are contained in the table accompanying the summary outline at the beginning of this chapter.

Prices of sand and gravel were under the jurisdiction of the Office of Price Administration, and on May 11 the General Maximum Price

Digitized by Google

Regulation froze prices at the maximum levels existing in March 1942. Subsequently the Office of Price Administration authorized upward revision of prices in a very few individual instances, but no general increases were approved.

NEW DEVELOPMENTS

Although molding-sand technology has been developing for hundreds of years in the metal industries, new attention is being directed to the subject owing to the complex problems of handling magnesium in the molten condition. The great expansion of magnesium-production facilities in 1942 stimulated interest and research, and technical articles explaining modern practice appeared.[3]

Before the war industrial sands from Belgium found a market in the Pacific Northwest, and a substantial tonnage enters this area from California, Illinois, and other distant States. In an attempt to determine the possibilities of developing local supplies of glass and molding sands, silica deposits in the State of Washington were investigated. A report on the subject was published.[4]

During recent peacetime years the Work Projects Administration has been an influential factor in the sand and gravel industry. On December 4, 1942, the President directed that, since increase in private employment had made the work-relief program no longer necessary, liquidation of project operations should be completed as soon as feasible. By taking this action it was expected that no project funds need be provided for the next fiscal year.

In spite of priority restrictions, many new plants were built in 1942, but most of them were comparatively small portable or temporary operations. Many producers whose permanent plants are well located to furnish civilian requirements compensated for a serious drop in this volume by operating temporary plants at other locations to serve war-construction demands.[5]

FOREIGN TRADE[6]

Even in peacetime years only minor quantities of sand and gravel were imported or exported. For example, during the period 1937 to 1939 imports averaged about 0.25 percent of domestic production and exports only about 0.02 percent. Foreign trade statistics for the 10-year period 1932–41 are shown in the accompanying table. Owing to wartime restrictions, no figures on current foreign trade can be published, but it is apparent from the data on sand and gravel recorded herein that their absence will not detract appreciably from the value of the report, particularly in view of the recent rigid restrictions on foreign movement of commodities. Foreign trade figures will be released at the termination of the present war emergency to preserve the continuity of the statistical record.

BLAST-FURNACE SLAG

The National Slag Association, continuing a policy begun in 1938, conducted a canvass of the 31 companies in the United States that prepare iron blast-furnace slag for commercial uses. The total output of air-cooled screened and unscreened and water-granulated slag for 1942 was 19,122,718 short tons, compared with 14,678,266 tons for 1941. Sales of air-cooled slag were 19 percent greater in 1942 than in 1941, and the average value per ton was 1 cent lower.

Air-cooled slag was used principally in the construction and maintenance of highways, access roads, airport runways, defense plant and housing projects, and miscellaneous structures; as railroad ballast; and for sewage trickle filters. Other uses and quantities involved are shown in the accompanying table.

Nearly all the commercial output is produced east of the Mississippi River, chiefly at steel centers in Ohio, Alabama, Pennsylvania, and Illinois. Shipments, however, are made into all States east of the Mississippi, except some of the New England States outside the economic range of sources of supply. Shipments of slag are made by railroad, truck, and waterway. The following tabulation shows the pattern of distribution during the past 3 years.

Digitized by Google

Shipments of commercial slag in the United States, 1940–42, by methods of transportation [1]

[Percent of total]

Method of transportation	1940	1941	1942
Rail	55	55	52
Truck	44	43	47
Waterway	1	2	1

[1] National Slag Association.

The average shipping range of blast-furnace slag in 1942 was 52 miles by rail, 17 by truck, and 117 by waterway. In most instances shipments did not exceed 140 miles by railroad, 35 by truck, and 160 by waterway.

During the process of crushing and screening blast-furnace slag, particles of metallic iron that escape through the slag notch of the blast furnace are recovered at the slag plant by hand picking and magnetic pulleys. During 1942 the companies surveyed reported 165,679 tons of metallic iron recovered and returned to the furnaces to bolster the supply of metal so vitally needed in the prosecution of the war. The yield slightly exceeds 1.2 percent or approximately 24 pounds of metallic iron per short ton of slag processed.

Not including those assigned to administrative, office, and sales activities, 1,629 plant and yard employees were engaged in producing commercial slag in 1942. The total number of man-hours in production was 4,168,539.

SUMMARY

The complete swing from peacetime to wartime construction in 1942 affected the gypsum industry adversely and general activity declined sharply. The over-all decrease in operations from 1941 may be measured by the 17-percent drop in new crude supply to a total of 5,099,084 short tons and the 24-percent slump in production of calcined gypsum to 3,045,082 tons in 1942. Markets for gypsum products were affected in diverse ways. Sales volumes of most products declined markedly from 1941, but these declines were compensated in part by the strong demand for cement retarder, agricultural gypsum, wallboard, and sheathing, of which sales advanced to record volumes in 1942. In addition, markets for laminated-board products expanded phenomenally after their introduction about the middle of the year. Principally as a result of the brisk demand for certain of the more highly processed, prefabricated products that command a higher price than other gypsum materials, the value of total sales by the industry declined only 9 percent from the record set in 1941 to a total of $63,170,744 in 1942. Although labor and material costs increased, prices of most gypsum products in 1942 were relatively unchanged from the levels that have prevailed in recent years. The General Maximum Price Regulation of the Office of Price Administration, effective May 11, froze prices of gypsum products at the highest selling value, f. o. b. mill, obtained during March 1942. Effective August 1, Maximum Price Regulation 188 of the same agency removed gypsum products from the general regulation and continued the March prices as maximum.

War controls on building construction by the Federal Government were the primary causes of the marked selectivity in demand for gypsum building products. The stoppage of nonessential public and private building by War Production Board Conservation Order L–41 of April 9 had an immediate effect upon the industry, and sales of lath, tiles, and nearly all building plasters slumped sharply after the first quarter of the year. The more restrictive revision of this order on September 7 and the establishment of review committees in War Production Board on October 22 to pass on essentiality of current and proposed construction both had adverse effects on sales of these

Digitized by Google

products. On the other hand, the joint War Housing Construction Standards of National Housing Agency and War Production Board of October 28 prohibited the use of lumber for housing when suitable substitutes were available and thus enlarged the markets for gypsum wallboard, sheathing, and laminated board.

[1] Each mine, plant, or combination mine and plant is counted as 1 establishment.
[2] Excludes byproduct gypsum.
[3] Made from domestic, imported, and byproduct crude gypsum.

The outstanding feature of the industry in 1942 was the steadily increasing demand for wallboard, sheathing, and the new laminated-board products. All of these are well-adapted to the current types of small, low-cost war and military housing which require prefabricated materials that are not high-priced and are quickly and easily erected with a minimum of labor. Although the advantages of these products would have assured a fair share of the market, the serious shortage of lumber undoubtedly helped increase demand for gypsum boards. Moreover, sheathing and laminated boards entered new fields of application, principally in nonresidential building, and were used widely as exterior siding and roof decks. For exposure to weather these products now are available with a variety of weather-resistant surfacing materials ranging from granule-coated asphalt roofing to a mill-painted finish. Laminated boards reportedly were accepted as satisfactory materials for farm construction work on which war controls were less restrictive than on housing. The effect of these factors was a 38-percent increase over 1941 in square footage of wallboard and a 110-percent gain in area of sheathing sold. The active demand for laminated products after their introduction in May 1942 is shown by sales of 53,170 M square feet (in terms of area of component board and not of finished product) valued at nearly 1½ million dollars.

In marked contrast to the record consumption of finished prefabricated gypsum building products, sales of the built-in materials—lath, tiles, and building plasters—fell sharply. In 1942 the square footage of lath sold was only half the record area sold in 1941, and the

Digitized by Google

long uptrend in demand for this product that started in 1934 was broken. Tile sales were more than one-fourth below and aggregate tonnage sales of building plasters (including Keene's cement) were 40 percent below 1941 volumes. Sales of "base-coat" and "gauging and molding" plasters, the important tonnage groups, slumped 45 and 39 percent, respectively, from the quantities sold in 1941. Indicated consumption increased only in the "insulating and roof-deck" group of building plasters, and sales were more than double the 1941 tonnage. This sharp gain reflects the high level of industrial building in which roof-deck plasters are used for poured-roof construction.

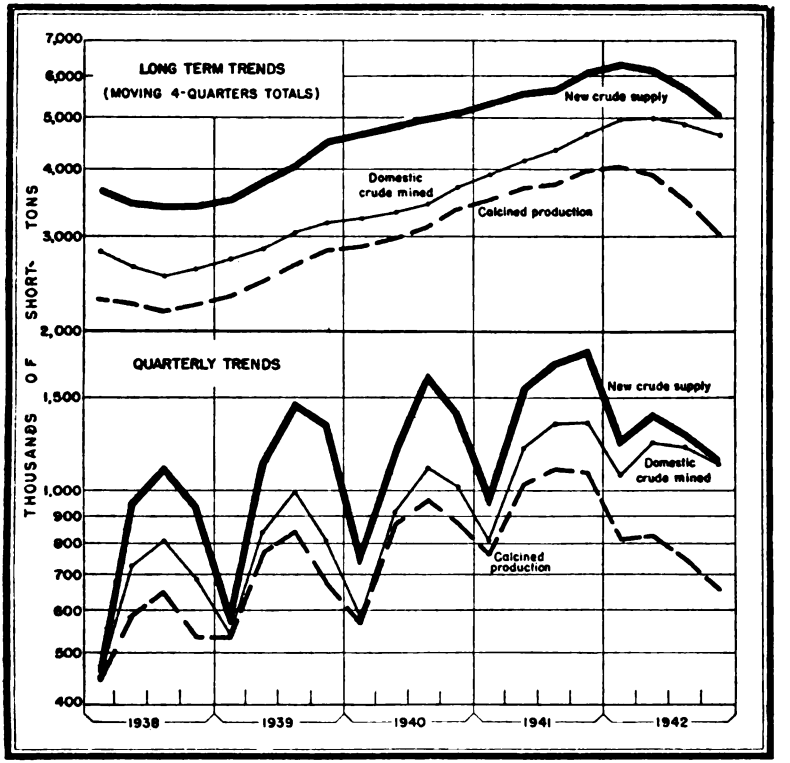

FIGURE 1.—Trends of new crude supply, domestic crude mined, and production of calcined gypsum, 1938-42, by quarters.

The source composition of the new crude supply in 1942 was changed markedly in that only 8 percent was derived from imports whereas in 1941 imported crude gypsum represented 22 percent of the total supply. Throughout 1942 the flow of crude from quarries in Nova Scotia and New Brunswick, Canada, to tidewater processing plants along the Atlantic coast was subject to Government war controls. Gypsum imports were placed on a quota basis, which was lowered drastically on January 21 and April 22. By August all company owned or leased gypsum boats had been requisitioned for other uses by the Federal Government or were lost at sea, and companies had great difficulty

Digitized by Google

in obtaining shipping space because of the relatively low preference rating assigned to gypsum. As a result crude imports in the last 4 months of 1942 were a mere trickle compared with normal volumes, and the total for the year fell 70 percent below the 1941 tonnage. In figure 1 the long-term trends of new crude supply and domestic crude mined show a marked discordance between the fourth quarters of 1939 and 1942. It is evident that the rate of imports advanced sharply in the October–December period of 1939 and continued at a relatively high level through the fourth quarter of 1941. This advanced rate probably represented efforts by importers to build up stocks in this country after the outbreak of war in Europe in September 1939. The marked parallelism in trends of new supply and calcined production throughout the 1938–42 period is notable. In 1942 convergence of the new-supply and domestic-crude curves and parallelism of the new-supply and calcined-production curves indicate that domestic material replaced imported crude chiefly in the markets for uncalcined products, although there undoubtedly was also some replacement in the calcined-products field.

The critical state of crude supplies at Atlantic tidal plants toward the end of 1942 was mitigated by the fact that the greater demand for gypsum products was in sections of the country not served from these plants. To help relieve the supply problem at importing plants in 1942, some domestic crude was shipped by barge from western New York to the New York City area, calcined gypsum from a domestic operation was moved by rail to a southern tidal plant, and the calcined output of a byproduct-gypsum plant was utilized in the New York City area. Total stocks of crude gypsum in the country on December 31, 1942, aggregated 741,549 short tons, of which 152,581 tons were at Atlantic tidewater plants. The only other recent stock data available are those for December 31, 1935, when there were two less calcining plants on Atlantic tidewater. At that time, stocks in the country totaled 668,927 tons, of which 178,919 tons were on the Atlantic coast.

The Department of Justice in September 1942 nol-prossed its criminal suit against two gypsum companies for illegal control of perforated-lath prices. An earlier criminal action was settled by a directed verdict of acquittal in November 1941. Of the three original actions [1] only the civil suit charging seven gypsum companies and officials with violations of sections 1, 2, and 3 of the Sherman Antitrust Act remains unsettled. Principal objectives of the civil action are to restrain these companies and individuals from violating the act and to have certain patents and agreements declared void.

Wage increases during 1942 were reported by some gypsum operators in New York, Michigan, Iowa, Utah, Nevada, and California. Despite the decline in demand for many products, there was a labor shortage in the industry in nearly all sections of the country. This shortage tended to increase operating costs, as producers were forced to overtime rates of pay to fill orders.

DOMESTIC PRODUCTION

Total output from domestic gypsum mines in 1942 showed a smaller proportional decline than did other general measures of industry activity and was only 2 percent below the 1941 tonnage owing to the necessity of supplanting imported supplies along the east coast and a strong demand for gypsum products in far Western and some Midwestern States. Of the 17 producing States, production was higher than in 1941 in 6, lower in 10, and was resumed in Arizona after a lapse of 2 years. The ranking States were New York, Michigan, Iowa, and California. Active operations totaled 64, of which 29 were underground mines, 30 open quarries, and 5 mine-quarry combinations.

The average value of run-of-mine gypsum advanced 3 cents over the 1941 figure to $1.45 per ton in 1942. As reported by producers this is a "plant" value, for little crude gypsum enters the open market. Data in the accompanying table relate only to natural gypsum and gypsite and do not include crude byproduct gypsum.

Crude gypsum mined in the United States, 1940–42, by States

State	1940			1941			1942

CALCINED PRODUCTION AND EQUIPMENT OF PROCESSING PLANTS

Production of calcined gypsum in 1942 dropped nearly one-fourth below kettle-and-kiln output in 1941 because of the slump in demand for building plasters after the first quarter of the year. In the 24 producing States 53 plants were active, of which 42 processed domestic crude, 10 imported crude, and 1 byproduct crude gypsum. Active calcining equipment in these plants comprised 172 kettles, 8 beehive kilns, 12 rotary kilns, and 4 grinding-calcining units. A canvass of the output of calcined gypsum by States was made for the first time for 1942; it showed the following distribution.

Digitized by Google

Calcined gypsum produced in the United States in 1942, by districts

District	Short tons	Value
New Hampshire, Vermont, Massachusetts, and Connecticut	91,788	$589,055
Eastern New York, New Jersey, Pennsylvania, Georgia, and Florida	500,011	3,390,693
Western New York	529,616	2,439,984
Ohio and Virginia	286,296	1,661,865
Michigan and Indiana	424,283	2,259,095
Iowa	324,387	1,476,107
Kansas and Oklahoma	159,585	853,532
Texas	285,430	1,202,266
Colorado, South Dakota, and Montana	73,893	446,562
Utah	20,695	122,303
California, Nevada, and Arizona	349,098	1,961,606
	3,045,082	16,403,068

Reflecting rising costs of labor, fuel, and materials, the average unit value of calcined gypsum, which is strictly a "transfer" value assigned by producers, increased 43 cents over the 1941 figure to $5.39 per ton.

Active calcining plants and equipment in the United States, 1940–42, by States

[2] Includes 4 grinding-calcining units.
[3] 1940: 1 calcining plant each in Arizona, Connecticut, Georgia, Indiana, Massachusetts, Nevada, New Hampshire, Oklahoma, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Florida, Kansas, Montana, New Jersey, Ohio, and Virginia. 1941: 1 calcining plant each in Arizona, Connecticut, Georgia, Indiana, Massachusetts, New Hampshire, Oklahoma, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Florida, Kansas, Montana, Nevada, New Jersey, Ohio, and Virginia. 1942: 1 calcining plant each in Arizona, Connecticut, Florida, Georgia, Indiana, Massachusetts, New Hampshire, Oklahoma, Pennsylvania, South Dakota, and Vermont; 2 each in Colorado, Kansas, Montana, Nevada, New Jersey, Ohio, and Virginia.

The active demand for gypsum board kept the 36 board machines in the country working at a high rate throughout 1942. Results of a monthly survey conducted by the Bureau of Mines for the War Production Board show that the over-all rate of operations of all board machines was 84 percent of capacity in September, 89 percent in October, 80 percent in November, and 75 percent in December. Generally, machines in Atlantic tidewater plants were less active than those in plants processing domestic crude. In the latter group machines were operated at 93 percent of capacity in September, 97 percent in October, 87 percent in November, and 81 percent in December. These capacity data are on a time-utilized basis in which 100 percent equals full operation for 85 percent of the total number of hours in each month.

DISTRIBUTION OF SALES BY USES

The marked changes from 1941 in distribution of total sales value among groups of products are traceable directly to differences in types of materials required for wartime compared with peacetime building. As shown in figure 2 the percentages represented by sales values of lath and building plasters (including Keene's cement) declined sharply from the 1941 distribution, whereas the value of all other boards (wallboard, sheathing, and laminated board) jumped to 50 percent of the total in 1942. Comparison of the distribution for 1928 and 1941 shows long-term changes in composition of sales for peacetime building. Notable differences are the increased percentage represented

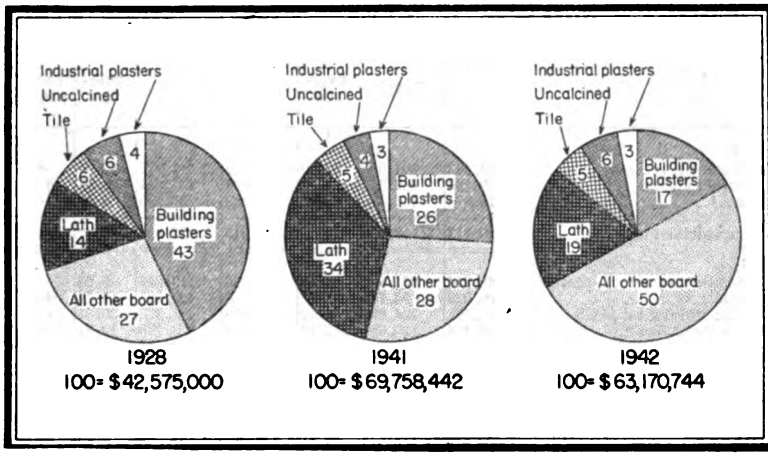

FIGURE 2.—Percentage distribution of total sales value, f. o. b. plant, of gypsum products in 1928, 1941, and 1942, by groups of products.

by value of lath and the decline in importance of the building-plaster group.

As a result of record consumption of portland-cement retarder and agricultural gypsum, total sales of uncalcined products advanced 15 percent over the tonnages sold in 1941. Unprecedented activity in the portland-cement industry raised indicated consumption of gypsum as retarder 8 percent over the record of 1941. Sales of agricultural gypsum increased 69 percent over the 1941 tonnage, a gain due to increased use in both major consuming areas—California and the Virginia-Carolina peanut section. In California, where "land plaster" is used on a large variety of crops to correct sulfate deficiency and to remedy black-alkali soils, consumption[2] has increased phenomenally, from 7,914 tons in 1934 to about 186,000 tons in 1942. In the Virginia-North Carolina area sales totaled approximately 60,000 tons, a 20-percent increase over 1941. A study[3] of markets for agricultural gypsum indicated possible expansion in the "southeast" and "southwest" peanut-growing sections of the country.

Digitized by Google

The aggregate tonnage of industrial plasters sold in 1942 declined 6 percent from 1941 because of the 62-percent slump in the plate-glass and terra-cotta group which was only partly compensated by sharply increased sales of all other types of industrial plasters. The decline in consumption of plate-glass and terra-cotta plasters resulted from the closing of the principal consuming market—polished plate glass for passenger automobiles.

In the cementitious group of building products only the insulating and roof-deck plasters showed increased sales over 1941; volumes of all other items declined sharply. Although sales of lath and tiles in the prefabricated group of products were markedly lower than in 1941, the loss was fully compensated by the record volumes of wallboard, sheathing, and laminated board sold. The decline in consumption of tiles was due to a decrease of nearly one-half in the square footage of

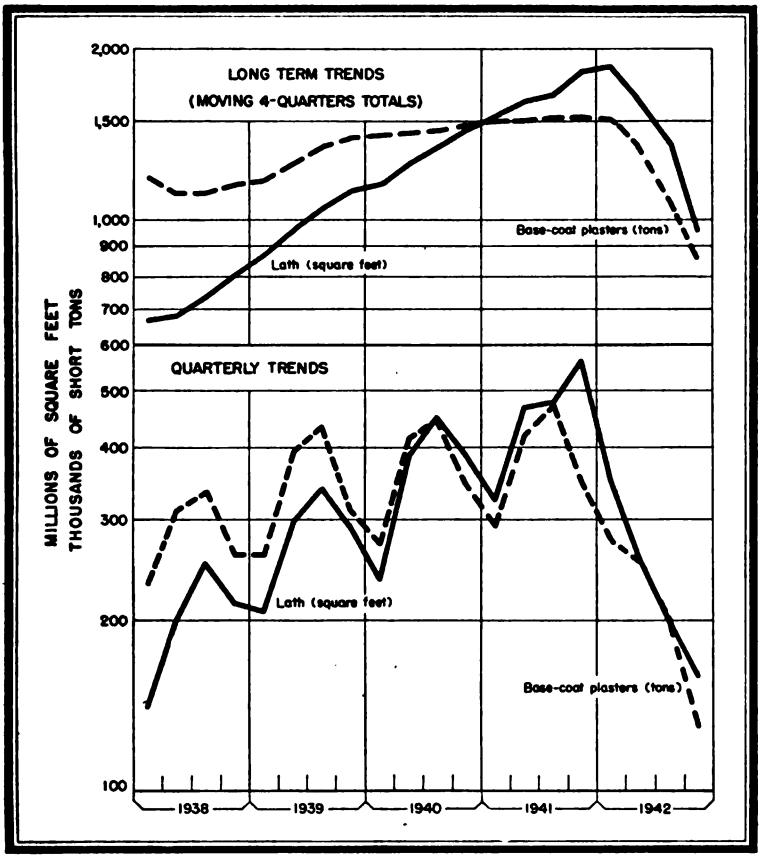

FIGURE 3.—Trends in sales of lath and base-coat plasters, 1938–42, by quarters.

partition tile sold and of approximately one-tenth in sales of all other tile shapes (roof, floor, soffit, plank, etc.).

The sharp change in trends of sales of lath and base-coat plasters early in 1942 is shown in figure 3, which was compiled from data in Bureau of Mines Quarterly Gypsum Reports. The annual volume of lath sold has increased each year since 1933 and after 1935 set new records each year through 1941. After a slight recession in 1938 sales of base-coat plasters also increased through 1941. The change in types of materials required for wartime from peacetime building resulted in a marked decline in demand early in 1942 for these "built-in" products, and sales fell rapidly to a fourth-quarter volume that was well below similar data for any of the years shown.

[1] Reportedly negligible square footages and values of sheathing are included under "Wallboard," 1928–38, inclusive.
[2] Per M square feet, f. o. b. producing plant.
[3] New product first marketed in 1942.
[4] Includes partition, roof, floor, soffit, shoe, and all other gypsum tiles and planks.
[5] Per M square feet, f. o. b. producing plant, of partition tile only.
[6] Reported as area of component board and not of finished product.

In the accompanying table listing annual data of the prefabricated gypsum products, average unit values are presented for the first time. Notable features of the series, not mentioned elsewhere in this chapter, are the over-all declines in average unit value of lath from 1930 to 1942 and in unit value of wallboard from 1932 to 1938, followed by a slight increase to 1942. Average values of wallboard vary more than those for lath because of annual fluctuations in demand for wallboard of different thickness and finish. The annual average values of partition tile likewise vary owing to changes in demand for the different thicknesses available. In studying price trends of gypsum products, it should be remembered that the industry experienced a disastrous price war in 1928–29.

PRICES

Prices of gypsum products as indicated by reported mill values showed a slight upward tendency in 1942, although no significant changes. Average mill values per unit have been remarkably stable in recent years. The decline from 1941 in average value of agricultural gypsum was caused by the increased tonnage of low-priced gypsite sold for such use in California. In 1942 the average mill value was $1.91 per ton for agricultural gypsum in California compared with $6.03 per ton for land plaster in the Virginia-North Carolina area where rock gypsum is used exclusively.

A study [4] of wholesale and retail prices of building materials states that gypsum plasters generally are marketed under a freight equalization system. The average wholesale and retail prices of plaster in September 1939 in the 50 cities surveyed were $13.58 and $17.57 per ton, respectively, a spread of 29.4 percent. Wholesale prices showed a fairly large geographical variation and were lowest in the Middle Atlantic and highest in the East South Central States.

RECENT DEVELOPMENTS

The most notable achievement in 1942 was the development of laminated gypsum-board products which are available at the mill with a wide variety of surfacing materials ranging from those suitable for exposure to weather to those for finished interiors without further decoration. The products are made in thicknesses up to 2 inches and are composed of two, three, or four plies of gypsum boards.

Use of gypsum plaster to make molds and cores for nonferrous metal casting is developing rapidly. A description [5] of the patented Capaco process, which utilizes a mixture of 79 percent calcined gypsum, 20 percent fibrous magnesium silicate, and 1 percent set accelerator, claims marked advantages for gypsum over sand molds. This process already is used in four casting plants, one of which has a daily capacity of 20,000 pounds of nonferrous metals.

In England patterns of gypsum plaster are used more widely than in former years as a means of speeding foundry work. Recent developments in production technique and the advantages of plaster patterns in foundry work have been described.[6]

Press tools of gypsum plaster made by direct molding have been investigated [7] in England for small-quantity production of metal pressings.

A new industrial use for gypsum is the forming of self-sealing liners for bulletproof gasoline tanks over molds of plaster.

Experience [8] has shown that the properties of a high-strength gypsum cement developed recently make it a satisfactory material for certain uses in cementing and shooting oil wells.

Preliminary work [9] on fusion of a mixture of salt, silica, and gypsum produced a glass free of bubbles and specks. Advantages of the

process are the volatilization of one-fourth of the iron content in the charge, which permits the use of low-grade silica, and the possible recovery of sulfuric and hydrochloric acids as byproducts.

In the late 1930's, practice at the New Caledonia nickel smelter was changed by substitution of gypsum for sulfur in the process as an economic measure. Approximately 6 tons of gypsum does the work of 1 ton of sulfur. At capacity operation monthly requirements [10] of gypsum by the smelter are 2,500 short tons, of which nearly all is obtained from local sources.

FOREIGN TRADE [11]

Nearly all the foreign trade of the United States in gypsum consists of crude gypsum imported from Nova Scotia and New Brunswick, Canada, to processing plants along the east coast as far south as Florida. Developments in 1942 in the flow of crude supplies are discussed earlier in this chapter.

Imports and exports of gypsum products are negligible in quantity and value in contrast with the volume of domestic business. Imports in the classes "Alabaster manufactures" and "Other manufactures" have declined sharply in recent years; they virtually ceased in 1942 because of the stoppage of trade with Italy, the principal source. In export trade the only significant change from 1941 was the trebling in square footage of exports of gypsum board owing doubtless to offshore construction activities of the Federal Government and to demand for board to repair bombed buildings in England.

WORLD PRODUCTION

World production of gypsum in 1942, based upon the meager data available, is estimated at approximately 9½ million metric tons.

Since the outbreak of war in 1939, output of gypsum in nearly all European countries that are large producers—France, United Kingdom, Russia, and Germany—undoubtedly has slumped because of the stoppage of residential building. The industries of those countries, unlike the United States, have not developed the manufacture of gypsum boards for which demand in 1942 has been so large in this country as to cushion the decline in plaster consumption. In European countries demand for gypsum as cement retarder probably is greater because of the increased activities of the portland-cement industries to fill needs for fortifications and other military purposes and for industrial and bombproof construction. Compensating in part for the decline due to cessation of building, consumption of gypsum and anhydrite as raw materials for the manufacture of sulfuric acid and sulfide and sulfate chemicals doubtless has gained appreciably in the past few years because of difficulties in obtaining supplies of sulfur and pyrite. After the World War of 1914–18 the processes utilizing gypsum and anhydrite were developed to economic feasibility in the laboratory, and commercial plants [12] employing them were in operation in the United Kingdom, France, and Germany at the outbreak of the present war.

In Spain, the only other European country with sizable production, output of gypsum probably has increased in recent years because of the necessary rehabilitation of buildings destroyed during the Civil War of 1936–39.

Activity of the gypsum industry in Canada during 1942, in terms of crude output, was only about one-third that in 1941. The decline was caused by the severe curtailment of crude exports to the United States and the halting by the Dominion Government of all building not essential to the war effort.

SUMMARY

The net effect of the change from peacetime to wartime economy in 1942 benefited the lime industry, and total sales of "open-market" lime advanced slightly over 1941 to a new record of 6,103,791 short tons. However, not all branches of the industry shared in the increased business. Sales of agricultural, chemical, and refractory (dead-burned dolomite) lime were well above the volumes sold in 1941, but sales of building lime slumped sharply from the 1941 tonnage. The first year of war also effected a marked change in demand for the two types of lime, as shown by the 7-percent gain in total quantity of quicklime sold and the 19-percent decrease in sales of hydrated lime from 1941. Although labor, fuel, and material costs rose sharply in 1942, prices of lime increased only slightly and remained in the narrow range of fluctuation that has prevailed for the past 10 years. The average value, f. o. b. plant, advanced 21 cents over 1941 to $7.27 per ton.

Although increases in hourly rates of pay were reported by producers in nearly all States, a serious labor shortage prevailed throughout the lime industry during 1942. Also, a high turn-over rate left many plants with an inefficient labor force. These factors increased production costs markedly, as operators were forced to pay overtime rates to meet the demand for lime. As selling prices showed little change from 1941, the increased costs and the short labor supply compelled many plants (mostly small producers) to close during 1942.

Other than price freezing, no direct war controls were imposed on the lime industry during 1942. The General Maximum Price Regulation of the Office of Price Administration, effective May 11, froze all lime prices at the highest selling value, f. o. b. plant, obtained during March 1942. Effective August 1, Maximum Price Regulation 188 of the same agency removed lime from the general order and continued the March prices as maximum. The stoppage of nonessen-

Digitized by Google

tial public and private construction by War Production Board Conservation Order L–41 of April 9 and its more restrictive revision of September 7 had direct adverse effect on sales of building lime.

The demand for chemical lime increased steadily throughout 1942 in nearly all sections of the country, and total sales for this classification advanced 6 percent over the former record tonnage sold during 1941. At the year's end, shortages had developed in several localities in which war plants with large lime requirements had been built or expanded, and supplies had to be brought in from relatively distant lime plants. Consumption of chemical lime by the various industries showed diverse effects of the war, and the quantities sold for many of the chemical uses declined in 1942 from 1941. However, most of the decreased requirements were in industries with relatively small consumption, whereas nearly all the large consuming industries, notably metallurgical, carbide, glass, and water-purification, purchased more lime in 1942.

Salient statistics of the lime industry in the United States, 1925–29 (average), 1935–39 (average), and 1940–42

[2] Figures cover January–September, inclusive.
[3] Data not available.

The high rate of operations and the installation of new open-hearth and electric-furnace capacities in the steel industry, the coming into production of new or expanded magnesium and Bayer alumina plants, and the increased quantities of metallic ores floated during 1942 raised the total demand for metallurgical lime 15 percent above 1941. The only reduced market for metallurgical purposes was for cyanidation of gold ores. The demand for lime in the Bayer alumina process doubtless will increase, because lime requirements per ton of ore rise rapidly as lower-grade bauxites are used. Owing to greatly increased requirements for acetylene in welding and synthetic rubber, consumption of lime for carbide manufacture advanced 49 percent over 1941. Demand for lime in glass manufacture and water purification also increased in 1942. The only chemical uses that annually consume large quantities of lime to show decreased consumption from 1941 were in the insecticide and disinfectant, paper, and tanning industries.

Digitized by Google

Sales of refractory lime reached a new high volume in 1942 and surpassed the 1941 tonnage by 15 percent—a greater proportional gain than was shown by output of steel. This increased demand resulted in part from the quantities needed for bottoms in new open-hearth furnaces and indicates continued substitution of dead-burned and stabilized dolomites for other higher-priced or less available refractories as well as wider acceptance of the enriched dolomitic-base materials.

War controls on the construction industry and the changes in types of materials required in wartime compared with peacetime building resulted in a sharp decline in total sales of building lime from 1941. As speed of erection was the first requisite of all wartime construction, the automatically reduced volume of masonry work caused a slump in consumption of lime for masonry purposes. Also, the demand for finishing lime declined markedly from 1941, because most of the war and military housing in 1942 consisted of small, low-cost units designed for the use of prefabricated rather than "built-in" materials.

Despite record farm income in 1942 and growing recognition of the importance of calcium as a plant food, consumption of agricultural lime increased only 5 percent over 1941. This increase compares unfavorably with the 38-percent gain in cash farm income from crops and Government subsidies in 1942 over 1941.

A notable feature of figure 1, which shows trends in major uses of lime from 1922 to 1942, is the rapid rate of recovery in sales of chemical and refractory lime from the low volumes of 1932. Consumption in these uses after 1935 set new annual records in each year through 1942, except in 1938, when sales declined. The building-lime curve

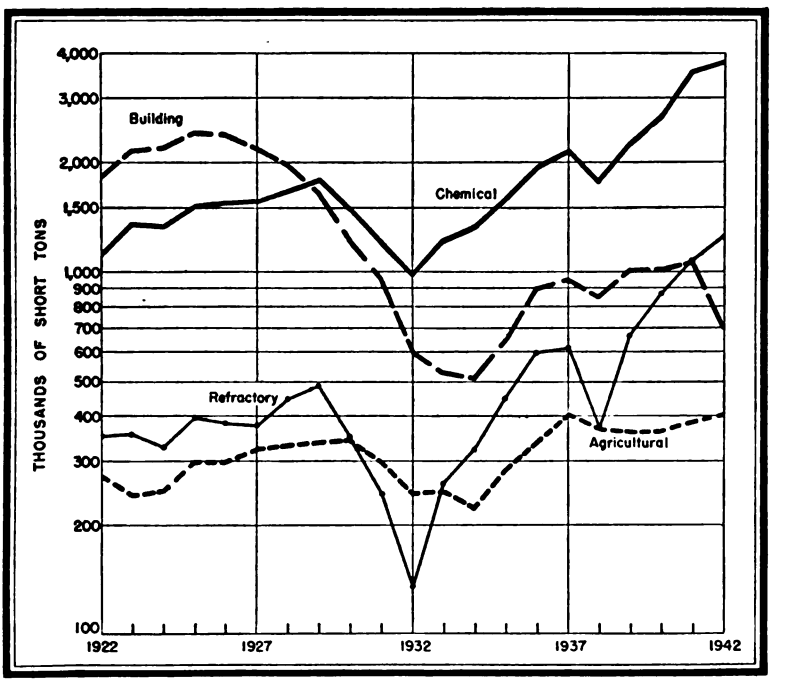

FIGURE 1.—Trends in major uses of lime, 1922-42.

Digitized by Google

shows the longest decline, extending from 1925 through 1934, with only partial recovery since that time. The demand for agricultural lime is more stable than for other uses, and annual sales show comparatively small fluctuations as well as the lowest rates of gain or loss. In contrast, sales of refractory lime have the greatest proportional fluctuation and also the most rapid rates of increase or decrease, as shown by the slope of the curve from year to year.

PRODUCTION

As quicklime is a semiperishable commodity and most plants have only small storage facilities, stocks of lime in the hands of producers are never large. Hence, in this chapter, the tonnages of "open-market" lime sold or used are considered equivalent to production and are used interchangeably.

Production of all classes of lime, by major uses, increased over 1941 except building lime, for which a decline of 35 percent was recorded. The largest proportional gain was shown in the output of refractory lime (dead-burned dolomite). It is noteworthy that the production of hydrated lime declined in all of the major use categories and that the decline in total output of this type from 1941 was 19 percent. The production of quicklime increased in all principal uses except for building purposes, for which output slumped 38 percent below 1941.

[2] By groups of States as follows—1941: Maine, Rhode Island, Connecticut, and New Jersey, 79,962 short tons valued at $639,559; North Carolina, Louisiana, Arkansas, and Oklahoma, 189,058 tons, $1,086,601; Minnesota and South Dakota, 63,655 tons, $186,436; Colorado, New Mexico, Montana, and Nevada, 91,780 tons, $586,696. 1942: Maine, Rhode Island, Connecticut, and New Jersey, 77,039 tons, $601,068; North Carolina, Louisiana, Arkansas, and Oklahoma, 102,282 tons, $802,373; Minnesota and South Dakota, 64,963 tons, $495,562; Colorado, New Mexico, Montana, Nevada, and Oregon, 125,082 tons, $872,703.

CAPTIVE TONNAGE

The lime industry, as defined by Bureau of Mines statistics, is limited as far as possible to operators who produce lime for sale to consumers. Captive tonnage of companies that produce lime for internal consumption is excluded with only a few exceptions. Hence the annual review figures are confined largely to "open-market" lime sold under competitive conditions. However, to obtain complete data on quantities of lime consumed for certain uses that are not covered by other Bureau of Mines statistics, it is necessary to include some captive tonnage. In 1942 the captive tonnage contained in the lime figures totaled 427,635 short tons valued at $2,239,152. This total comprised 11,429 tons of lime for making prepared masonry mortars, 312,557 tons for metallurgical uses (of which approximately half was for steel manufacture and half for ore concentration), 16,864 tons for miscellaneous chemical uses, and 86,785 tons of refractory lime. The

Digitized by Google

approximate total consumption of lime in alkali, carbide, glass, magnesia (85 percent), paper, and sugar manufacture may be ascertained by combining the "open-market" lime figures for these uses with the statistics (after allowances for calcining loss) on similar uses for limestone in the Stone chapter of Minerals Yearbook. The figures in the Stone chapter include limestone used to make captive lime but exclude the stone used to produce "open-market" lime.

PRODUCTION BY STATES

The first year of war effected sharp changes in the location of production of lime from 1941. The record output of 1942 was obtained from 270 plants in 37 States and 2 Territories; production increased in 16 States and 2 Territories and declined in 21 States from 1941. No production was reported for Idaho in 1942. The ranking producing States, in order of tonnage, were Ohio, Pennsylvania, Missouri, and West Virginia, which together supplied 61 percent of the total. Although the slump in building lime had a marked effect on production in Ohio, the strong demand for refractory and chemical lime offset the loss in part, and output declined only 8 percent from 1941. Production in the other 3 ranking States that are large producers of chemical lime was greater than in 1941.

In 1942 only 270 plants were active compared with 309 in 1941. Nearly all the plants forced to close by labor, price, or other reasons directly attributable to the war were small producers. The greatest number closed in Pennsylvania, in which 27 plants ceased operating either temporarily or permanently.

PRODUCTION BY USES

In 1942 the largest gains over 1941 in tonnages of lime consumed in the principal uses were recorded for metallurgical and refractory (dead-burned dolomite) purposes and for the manufacture of calcium carbide.

In this chapter, data on the production of lime for its many uses are presented in one table, whereas in former annual reviews the figures were listed in two tables, one for the major uses and a second for miscellaneous uses of chemical and industrial lime.

Lime and other liming materials used in agriculture.—Although production of lime for agricultural purposes gained 5 percent over 1941, the increase was in much smaller proportion than that reported for cash farm income. The output in Pennsylvania, the State with the largest production for agriculture, declined 3 percent from 1941, owing doubtless to closing of a large number of the small plants because of labor shortages.

In the markets for liming materials, lime lost further ground to ground limestone or "agstone," production of which increased 15 percent over 1941. Of the other materials, the output in 1942 of crushed oyster shells declined slightly and that of marl increased somewhat compared with 1941.

Calcareous marl	183,009	76,860	175,393	.96	194,878	81,850	135,046	.69

[1] Effective lime contents as follows: Quicklime, 85 percent; hydrated lime, 70 percent; limestone and oyster shells, 47 percent; calcareous marl, 42 percent.
[2] Figures supplied by Fish and Wildlife Service.
[3] Preliminary figure.

Building lime.—Production of lime for all building purposes declined sharply from 1941. The degree of slump, however, was more marked for finishing and mason's lime than in lime used to make prepared masonry mortars.

Chemical and industrial lime.—Of the principal chemical uses of lime, only the paper, tannery, and insecticide, fungicide, and disinfectant uses required less lime than in 1941. In paper, the decline resulted from reduced activity in that industry owing primarily to a shortage of wood for pulping.

HYDRATED LIME

Production of hydrated lime had increased each year from 1938 through 1941, but the output in 1942 was sharply lower than in 1941. The degree of change was much more severe than that customarily shown in year-to-year fluctuations in demand for hydrated lime.

The 1942 output of hydrated lime was obtained from 165 active plants in 35 States and 2 Territories; production increased over 1941 in 10 States and 2 Territories, decreased in 20 States, and was relatively unchanged in 3 States. In 1942 no production was reported in South Dakota, and the manufacture of the hydrate was started in Louisiana and Oregon. Ranking States, in order of tonnage, were Ohio, Pennsylvania, and Missouri, which together supplied 58 percent of the total.

Uses.—Consumption of hydrated lime was lower in all its principal uses except water purification.

TRENDS IN PRINCIPAL USES

Trends in major uses of lime in the 1922–42 period are shown in figure 1 and discussed earlier in this chapter. Figure 2 illustrates clearly the marked changes effected by the war on the percentage distribution of lime in its major uses in 1942 from 1941 and also the more pronounced long-term changes from the 1925–29 period.

The fairly close correlation of refractory lime with steel-ingot production in the 1932–42 period is presented in figure 3. The discordance in recent years between the metallurgical-lime and steel-production curves results partly from increased consumption of lime in the Bayer alumina process and partly from increasing requirements per ton of steel owing to the lower quality of scrap used and the wider use of ore in place of scrap.

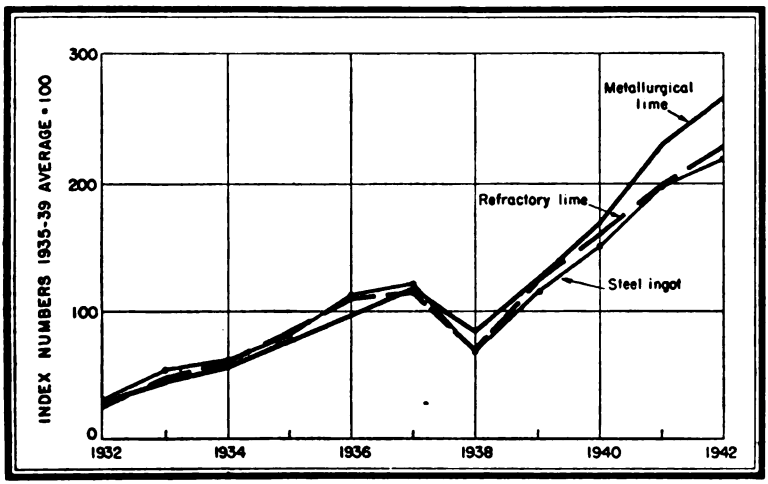

FIGURE 3.—Indicated annual consumption of metallurgical and refractory lime compared with steel production, 1932–42. (Index numbers of steel production by Federal Reserve Board.)

[1] Less than 0.1 percent.

PRICES

Average values for total sales of building quicklime are higher than for building hydrate, an anomalous condition compared with values of types of agricultural and chemical lime. This condition results principally from the rather widespread use of the relatively higher-priced pulverized quicklime in building. It also is noteworthy that some producers in nearly all sections of the country generally obtain a higher price for bulk quicklime than for bulk hydrate for all uses, although the most common practice is to set a higher value on the hydrate.

NEW DEVELOPMENTS

A new type [1] of limekiln designed to calcine small sizes of stone was introduced in 1942.

Descriptions [2] of the properties and methods of manufacture of dead-burned, stabilized, and enriched dolomite-base refractories were published.

PLANT CAPACITY

In 1942 about 72 percent of total capacity (based upon a 300-operating-day year) was used in the country. Data on capacities of calcining equipment (excluding obsolete units) are listed in the following table, by types and districts.

[1] Ellerbeck, T. R., Vertical Kiln of New Design Calcines Smaller Sizes of Crushed Limestone: Pit and Quarry, vol. 34, No. 11, May 1942, pp. 55–58.
[2] Schallis, Alvin, Dolomite-Base Refractories: Bureau of Mines Inf. Circ. 7227, 1942, 11 pp.

SIZE OF PLANTS

There has been a strong trend toward larger lime plants, as is shown by comparison of data on size groups in 1942, the year of record production, with those in 1925, the preak production year of the 1920's. In all groups under 25,000 tons, both the number of plants and the percentage of total output from each group declined sharply. The number of plants in all groups over 25,000 tons increased, and the percentage of total output increased for each group except the group 50,000 and less than 100,000 tons. The largest gain in percentage of total production was in the group over 100,000. The marked decline in total number of plants from 1925 took place entirely in the groups under 25,000 tons. These data on size of lime plants are not comparable with those on companies and plants published in these chapters in recent years. The earlier studies are based only upon size of companies.

Distribution of lime (including refractory) plants in 1925 and 1942, according to size of production

Size group (short tons)	1925			1942		
	Plants	Production		Plants	Production	
		Short tons	Percent of total		Short tons	Percent of total
Less than 1,000	172	40,054	1	48	17,844	
1,000 and less than 5,000	86	246,433	5	72	195,265	3
5,000 and less than 10,000	65	478,336	10	28	192,497	3

FOREIGN TRADE

Because of wartime restrictions, no figures on imports and exports can be published. However, foreign trade of the United States in lime has a negligible effect on the domestic industry.

Imports.—During the 1935–39 period, annual imports of lime (including dead-burned dolomite) averaged 14,108 short tons valued at $240,909. This represents only 0.4 percent of average annual domestic production of 3,692,397 tons during 1935–39. In 1940, the last year for which data are complete, 9,205 tons of lime valued at $81,888 were imported or only 0.2 percent of domestic output. The principal volume of imports is from British Columbia, Canada, into the the Pacific Coast States, a flow in 1940 that comprised 98 percent of the total. Imports increased in 1941 and for the January-September period were at a monthly rate of 1,018 tons, which was 33 percent above the rate (767 tons) of 1940. Imports doubtless increased in 1942 over 1941, owing to shortages of lime on the West Coast, which were overcome by bringing in Canadian material.

Exports.—Annual exports of lime in the 1935–39 period averaged 10,905 tons valued at $123,167—a volume that represented only 0.3 percent of the average annual domestic production of 3,692,397

Digitized by Google

tons during the same period. During 1940 a new record of 31,912 tons (0.7 percent of domestic output of lime) was exported. The volume of exports increased further in 1941 and for the January-September period was at a monthly rate of 3,605 tons—a 36-percent gain over the monthly rate (2,659 tons) of 1940. Exports in 1942 undoubtedly advanced over 1941 owing to expanding markets in the Latin American countries and in eastern Canada.

GENERAL SUMMARY

The reaction of the various segments of the clay industry to wartime conditions emphasizes the fact that, although there is considerable overlapping in many fields, the physical properties of the various clays have enabled each clay to dominate one or more specialized markets. Production of some clays increased while others decreased, depending on the extent to which each contributed to an increasingly military economy. Shipments of fire clay have nearly doubled since 1940, and even those clays that declined from 1941 held at levels comparing favorably with recent peacetime years. Over-all, 4 percent more merchant clay was shipped in 1942 than in 1941.

As clays are available in more than ample quantities, no restrictions in their use were imposed by the War Production Board; in fact, their application as substitute materials was encouraged. Many examples of such substitute products appeared, but the total consumption of clay in them was insignificant.

The restrictions felt by the clay industry were those that developed from wartime shortages in such things as metals, equipment, and labor. Only fire clay was regarded as critical enough to warrant granting special priority ratings for repair and expansion programs. As time went on, labor became increasingly scarce. In isolated instances plants reported that they could not maintain sufficient production to fill all orders; but, in general, reduced crews met the sales demand. Shortages of hardware, plumbing, and lumber led to allocations of available supplies to war construction and discouraged a general private-building program. Transportation was a problem in many areas. Under the stress of accumulated difficulties, a few plants suspended operation for the duration of the war; but the great majority, although granted no advantages, found ways of solving their problems and maintained production.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce. Domestic figures for fuller's earth compiled by R. W. Metcalf, of the Bureau of Mines.

Digitized by Google

Prices of all clays were under the jurisdiction of the Office of Price Administration. The General Maximum Price Regulation froze prices at the maximum levels of March 1942. Many producers complained that various expenses, such as costs of labor, transportation, and repair parts, had risen since their prices were established, and a few petitioned the Office of Price Administration for relief. Some of the cases were under consideration at the end of the year, but none had been approved.

Foreign trade in clays was reduced materially during 1942. Imports consisted principally of kaolin and ball clay from the United Kingdom, and exports (which totaled 193,199 tons) were 61 percent fire clays.

Interest in clay as an ore of aluminum reached a point at which large sums of money were expended by both private concerns and Government agencies in research and exploration programs. This development may prove to have primary importance in the future, although many obstacles must be overcome before clays will be able to compete with bauxite upon an equal basis.

Bureau of Mines statistics reported in this chapter are limited to those tonnages of clay that are sold or shipped raw by the producer. Any departures from this rule are clarified in the text. The tonnages do not include the much greater quantity of clay mined by manufacturers of brick and other clay products at integrated plants at mine or pit.

CONSUMPTION AND USES

The accompanying table gives sales of specified domestic clays by kinds and uses in 1942, continuing a series begun in 1921. Of particular interest in 1941 and 1942 have been the sharp increase in refractory and foundry clays, the apparent recovery in fuller's earth, and the decrease in rubber clay.

Figure 1 shows the contributions of the clays to refractory uses during the past 10 years.

CHINA CLAY OR KAOLIN

Shipments of kaolin or china clay by domestic producers were 13 percent lower in both quantity and value in 1942 than in the record year 1941. Although this might be interpreted as indicating a period of recession, further comparisons show that activity was high. More domestic kaolin was shipped in 1942 than in any previous year except 1941, 14 percent more than in 1940, and 45 percent more than the average in the years 1935–39.

Mine shipments were reported in 14 States, but most of the tonnage came from Georgia and South Carolina. Georgia, furnishing 79 percent, contributed an even greater portion of the national total than usual, and South Carolina ranked second with 12 percent.

Digitized by Google

Outstanding changes in kaolin consumption compared with 1941 were the 60-percent reduction in its use in rubber, 16-percent in pottery, and 8-percent in paper and the 30-percent increase in refractories. The drastic decline in sales to the rubber industry was a direct result of the rubber shortage, but recovery in this use is to be expected if synthetic rubber technology does not require the use of materials that will displace clay. Although pottery requirements were not as great as in 1941, shipments in 1942 compare favorably with those in previous years. As paper clays constitute approximately 60 percent of the total kaolin tonnage, even the 8-percent reduction resulting in part from a paper-production curtailment order by the War Production Board constituted a serious loss. However, comparisons show that kaolin sales to the paper industry were greater in 1942 than in any prior year except 1941. Wartime expansion of the high-temperature manufacturing processes sharply stimulated consumption of kaolin in refractories.

In addition to shipments of raw kaolin, producers reported to the Bureau of Mines that 194,234 tons were burned into clay products at the mine or pit.

Although kaolin is not yet a commercial source of aluminum metal, many deposits were investigated as possible sources.

Kaolin beneficiation plants equipped to recover mica as a byproduct of clay production enjoyed a very active market during 1942. During the latter part of the year a shortage of ground mica developed, and a movement was initiated to obtain price concessions from the Office of Price Administration to stimulate production.

Crude undried kaolin sold as low as $2.50 per ton for refractory uses, and processed grades sold all the way up to $20 for air-floated enamel quality. Specialties were listed at $20 to $40 per ton. Most paper clays ranged from $7.50 to $15 and rubber clays from $8.50 to $20 per ton. The national average value, as reported by producers to the Bureau of Mines, was $8.49 per ton, or slightly higher than the $8.46 in 1941 and $8.39 in 1940.

Imports of china clay in 1942 totaled 63,278 tons valued at $671,081, 26 percent less than the 85,141 tons valued at $901,973 received in 1941; the United Kingdom supplied 62,774 tons, and the remainder (504 tons) came from Canada. The English clay was valued at $10.59 per short ton, approximately the same as in 1941, but transportation added materially to the delivered price in this country. Trade journals quoted lump clay, f. o. b. American ports, c. i. f., at $19 to $28 and air-floated at $40 to $60 per long ton.

Kaolin exports are not recorded separately by the Department of Commerce, but producers reported to the Bureau of Mines that in 1942 they exported a total of 2,128 tons valued at $19,216 to Canada, Mexico, and South America.

BALL CLAY

Compared with 1941, total sales of ball clay decreased 18 percent in 1942 in both tonnage and value, but in spite of this reduction they were the second highest on record. Approximately 49 percent of the total in 1942 was mined in Kentucky and 43 percent in Tennessee; the remainder came principally from Maryland and New Jersey. Mississippi and Missouri reported minor quantities and Nevada none.

Imports of "common blue and ball clays, unwrought and unmanufactured" from the United Kingdom fell to 19,648 short tons in 1942, or 27 percent from the 26,817-ton total for the previous year. The average value was $9.21 per ton compared with $9.06 in 1941. Thirty-four tons valued at $885 were received from Brazil and 102 tons valued at $903 from Canada.

During recent years domestic producers have improved and standardized the quality of their product to a degree that has gained its acceptance in the field formerly held by foreign ball clays. In prewar years domestic ball clay could be laid down at consumers' plants at a lower price than imported; this advantage was an even greater factor in 1942, when ocean freight rates were excessively high. Displacement of the entire foreign tonnage is unlikely, however, as strenuous efforts are being made by English clay producers to retain their position in the American market.

The average value of domestic ball clay as reported to the Bureau of Mines by producers was $8.49 per ton, slightly higher than the $8.45 of 1941 and substantially more than the $7.57 realized in 1940. Prices were limited by the General Maximum Price Regulation, and

Digitized by Google

trade-journal quotations listed bulk, shredded, at $3 to $8.25 and air-floated, in bags, at $10 to $18.25.

War conditions stimulated consumption in refractories, kiln furniture, and paint filler. Decreased amounts were required for products devoted principally to the needs of the civilian economy, such as pottery, paper filler, and linoleum, but these requirements compared favorably with consumption in the same categories in most pre-war years. Eighty-five percent of the domestic ball clay shipped in 1942 was used in whiteware or cream-color ware and 6 percent in high-grade tile.

FIRE CLAY

Intense wartime activity in the metal-working and other high-temperature process industries continued to absorb increasing quantities of refractories. Shipments of domestic fire clay were 16 percent greater in 1942 than in 1941, establishing a new record for that portion of the fire-clay tonnage that is sold or shipped raw to distant plants for further processing or ultimate consumption. In addition to this merchant clay, producers reported that 3,457,413 tons of fire clay were burned into firebrick or other clay products in integrated plants at the mine or pit, 6 percent more than the 3,275,021 tons burned in 1941.

At the beginning of the rearmament program, the fire-clay refractories producers, who for years had been operating at less than 50 percent of capacity,[2] had enough active equipment to handle immediate demands. In addition, obsolete and inactive plants and facilities represented a considerable capacity. As the tremendous construction and modernization programs in the steel, coke, magnesium, aluminum, power, glass, and other industries got under way, refractories were supplied as needed with few delays in delivery. The War Production Board gave close attention to the situation, but the establishment of rigid controls did not become necessary. Virtually all that was required was an occasional meeting of a committee representing members of the industry and the War Production Board to relieve some local shortage. As demand increased, more and more obsolete facilities were rehabilitated and improved to meet requirements without construction of new plants. It has been esti-

[2] Ramsay, John D., Refractories the Backbone of Industry: Penton Press, Cleveland, Ohio, 1941, p. 78.

Digitized by Google

mated that, in contrast to the mushroom growth of the consuming industries, only about 10 percent of new capacity in the form of new plants and expansion or modernization of old ones has been added to the refractories industry.[3] Although there is some minor amount of unused additional facilities, the industry was considered to be operating at close to capacity at the end of 1942. It is expected that, barring major production interruptions, all demands can be met.

Shipments of fire clay were reported from 29 States in 1942. Although production is widely distributed, the major tonnages are concentrated in relatively few States owing to market and quality factors. Pennsylvania supplied 26 percent of the total, Missouri 23, Ohio 16, California 9, and Kentucky 9; thus, these five States shipped 83 percent. A map showing location of fire-clay mines in the United States was published in the chapter on Clays in Minerals Yearbook, 1941.

Fire clay has a wide variety of uses, many of which in normal times consume substantial quantities, but in 1942 over 90 percent went into refractories.

According to the records of the Department of Commerce, 118,101 tons of fire clay valued at $709,455 were exported in 1942, principally to Canada, England, and Mexico, compared with 91,732 tons valued at $721,627 in 1941. This 29-percent increase in fire-clay exports contrasts sharply with the 35-percent reduction in exports of all other clay. It is apparent from these figures that substantial quantities of American clay bolstered the munitions production of our allies.

Imports of fire clay have not been an important factor in recent years. Facing competition from American fire clays, Gross-Almerode had even in pre-war years declined to a few hundred tons per year. Klingenberg clay was prized by American graphite crucible makers, but it has been largely replaced by American clays.[4] Obviously neither of these German clays was imported in 1942, but suitable domestic substitutes are available.

In 1942 the average value of merchant fire clays—$2.35 per ton—was somewhat lower than the $2.44 reported for 1941. Prices were frozen at March 1942 levels by the General Maximum Price Regulation.

BENTONITE

Bentonite enjoyed a good market in 1942; output, which increased 6 percent over 1941, reached a new record. Wyoming produced slightly less than in 1941 but was still the leading producer, with 37 percent of the total. South Dakota increased shipments by 54 percent and supplied 24 percent of the total. In 5 years South Dakota has more than quadrupled its bentonite output. Reflecting the high quality of the bentonite from the Wyoming-South Dakota district, its 61 percent of the national tonnage commanded 76 percent of the value. For the entire United States the average value in 1942 was $6.80 per ton, which compares with $6.93 in 1941 and $7.65 in 1940.

Of the 1942 shipments, 40 percent was used in foundries and steel works, 31 percent for filtering and decolorizing oils, 13 percent in oil-well drilling muds, and the remaining 16 percent in a wide variety of applications. Foundry consumption was higher, in line with metal activity. The use of bentonite in foundries, where its bonding properties are valuable, increased from 53,872 tons in 1939 to 149,384 tons in 1942. The decrease in oil-well drilling reduced that market, but requirements for oil filtering held close to the level of 1941.

Some of the principal firms increased their production capacity substantially over that in 1941, but this probably was not a strong factor in reduction of the average value, which likely resulted from the increased proportion of material sold for foundry work—a comparatively low-priced grade.

Although some mine-run material is sold as low as about $2 per ton, in general prices ranged from about $4 for unprocessed material through various pulverized grades, mainly in the $7 to $20 span, to a maximum of about $35 per ton for extremely finely divided products.[5]

In oil refining, bentonite is directly competitive with fuller's earth, as well as with other materials discussed in the fuller's earth section of this chapter. Usually the bentonites and sub-bentonites used for this purpose have little natural bleaching capacity, but when acid-treated or activated they are converted into very effective bleaching agents. As it is often difficult to distinguish between these two clays there has been some reclassification by producers in past years. Although the Bureau of Mines as a rule accepts the producer's classification of his commodity, this type of discrepancy is held to a minimum wherever feasible.

The same is often true of those clays used as rotary-drilling muds. For this use, clays having bentonitic characteristics have particular value for suspending cuttings and maintaining a desirable specific gravity. The boundary between bentonite and other clays of somewhat similar properties is sometimes hazy, and drilling muds that are not obviously bentonite are classed among the miscellaneous clays.

Exports, as reported by producers to the Bureau of Mines and excluding foreign shipments made by dealers and a large tonnage of acid-treated bentonite used for oil refining, totaled over 10,000 tons. Destinations listed were Australia, England, Mexico, and various South American countries.

FULLER'S EARTH

Shipments of fuller's earth were only 2 percent less in 1942 than in 1941, in spite of a considerably greater reduction in oil-refining activity. The mineral-oil refining industry consumed 84 percent and the vegetable-oils 10 percent of total shipments.

Although during the past 20 years fuller's earth has depended largely on the petroleum industry, it has not participated fully in that industry's expansion. As illustrated in figure 2, during the 1920's consumption of fuller's earth increased in direct proportion to petroleum output, but in the 1930's it lost ground almost continuously. The decline in use of fuller's earth was due to the increased popularity of colored fuels, to improvements in refining methods, and even more directly to the fact that it was forced to meet the competition of materials like bauxite and synthetics that have properties desirable in refining oils. Although the first cost of the competitive products is not low, their greater durability makes them economical. Activated earths have also made deep inroads into the market for natural bleaching clays.

The same active competition has carried over into catalytic petroleum cracking, which developed rapidly during the 1930's. Fuller's earth has had a somewhat varied acceptance as a catalyst, but research has developed a specially treated product that is to be used in some of the new high-octane plants.[6]

[6] Information furnished by Petroleum Administration for War.

Digitized by Google

The decline in consumption of fuller's earth was arrested in 1941 and, when compared with petroleum refining, relatively more was used in 1942. People in the industry believe that although this may have resulted from some tonnage being absorbed into plants under construction and not yet operating, it is more likely that in some refineries the pressures of wartime production have led to somewhat earlier rejection of fouled earth, thus increasing the clay used per unit of petroleum product.

Only part of the recovery in 1941 can be attributed to reclassification of borderline material and no additional reclassification took place in 1942, so the evidence indicates that the long downward trend may have run its course.

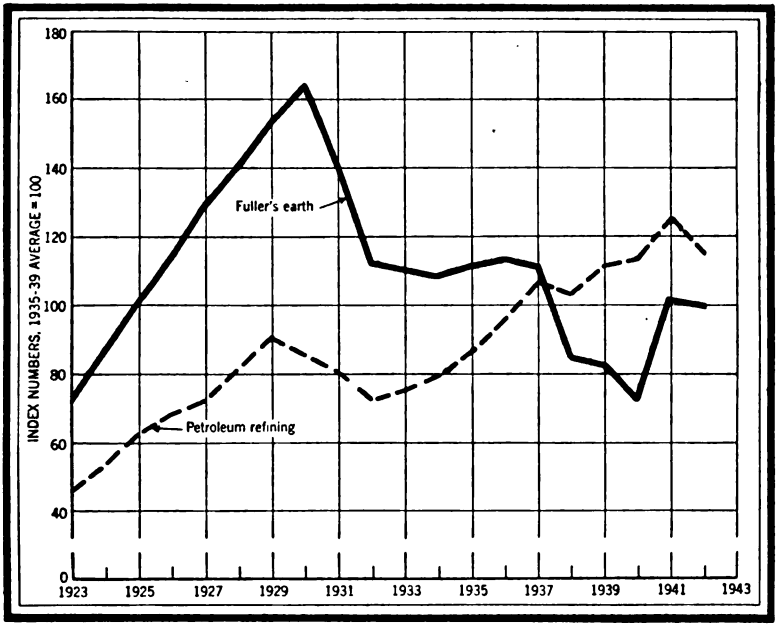

FIGURE 2.—Mine shipments of fuller's earth compared with petroleum-refining activity (Federal Reserve Board Index), 1923–42.

Texas was the leading fuller's earth-producing State in 1942, with 42 percent of the total; the Florida-Georgia district contributed 41 and Illinois 15 percent. The average value of Texas clay, however, was only $8.38 per ton as compared with $8.70 for Illinois and $13.14 for Florida-Georgia. Fuller's earth has many grades, and some have relatively rigid specifications; thus, prices usually range from $5.50 to $16 per ton in most areas, depending on the mesh size and degree of preparation.

In recent peacetime years imports of fuller's earth have been limited to relatively expensive materials equivalent to 1 or 2 percent of domestic production. By 1942, imports had shrunk to an insignificant 287 tons, all from the United Kingdom and valued at $4,716 ($16.43 per ton); in 1941, 342 tons valued at $5,042 entered the country.

Digitized by Google

Exports reported by producers to the Bureau of Mines were more substantial—6,052 tons valued at $50,080 in 1942. Shipping shortages took their toll, however, as these totals are much less than the 10,722 tons valued at $98,847 reported for 1941.

MISCELLANEOUS CLAYS

This classification is simply a grouping of various clays that do not fit logically into any of the types discussed elsewhere in this chapter. As is apparent from the foregoing table of uses, the clays utilized in making common brick, sewer pipe, and other heavy-clay products constitute the major part of the tonnage, followed by much the same type of material used in cement manufacture. Third in importance are the finely divided clays that are applied alone or admixed with bentonite and other constituents to produce rotary-drilling mud. Small quantities of slip clay are also included. Owing principally to the decrease in oil-well drilling and the declining demand for heavy-clay products, 16 percent less miscellaneous clay was shipped in 1942 than in 1941.

Most of these clays and shales are valued at less than $1 per ton; but the average for the class is usually somewhat higher owing to the inclusion of drilling mud, much of which sells for around $10 per ton, and other high-priced specialties like slip clay.

It must be emphasized that merchant clay is only a small part of the clay and shale used in heavy-clay-products manufacture. Usually such products are made in plants at or very near the mine. Producers canvassed by the Bureau of Mines reported that in 1942 they burned over 8,500,000 tons into clay products at the mine or pit, but additional large quantities were made into heavy-clay products at the mine or pit by firms not canvassed by the Bureau of Mines. A more complete coverage of the industry is in prospect. The Bureau of the Census reported that 16,062,000 short tons of clay were produced in 1939 by the common-clay and shale industry. Although only fragmentary information is available since that time, owing to suspension of the canvass by the Census of Manufactures, it is estimated that the quantity was about 10 percent greater in 1941. Further information on this part of the industry appears in the following section on Clay Products.

Similarly, clay marketed for cement manufacture is only a small percentage of the total clay so used. In 1942, 287,639 tons of mis-

Digitized by Google

cellaneous clay were reported sold to cement companies, but the cement industry reported to the Bureau that it used 5,181,582 tons of clay and shale in 1942, nearly all of which was mined by the cement companies on their own properties.

As most of the miscellaneous clays are cheap and abundant throughout the world, foreign trade in them is limited to higher-priced specialties. Official Department of Commerce figures do not reveal the exact total for 1942, but it is known to be small, as exports of only a few hundred tons were reported by producers to the Bureau of Mines.

CLAY PRODUCTS

Although the demand for structural clay products was active during the early part of 1942, it declined with the downward trend in building activity. According to figures gathered from various sources and issued by the Statistics Division, Materials Branch, War Production Board, covering glazed and unglazed common and face brick, unglazed hollow facing tile, and unglazed structural clay tile, production of brick or brick equivalent was 25 percent less in 1942 than in 1941. This group of producers has operated at far less than capacity for years and operated at only 36 percent of capacity in 1942.

Consumption of these materials was encouraged by the War Production Board for both permanent and temporary structures, because a minimum of critical materials was involved, and production has been mechanized so that of 33,000 men employed in the brick and tile industry, 28,000 were either unskilled or semiskilled. In addition, transportation can be saved as the War Production Board claims there is a clay-products plant within 100 miles of every likely building-construction site in the United States.

Digitized by Google

Imports are negligible. Exports are not big factors in the industry, but appreciable tonnages are shipped as follows: 81 percent to Canada, 11 percent to South and Central America, and 8 percent to other destinations.

TECHNOLOGIC DEVELOPMENTS

During the past few years there has been a steadily increasing interest in the possibility of utilizing clay as a source of aluminum. Up to the present the United States has depended on high-grade bauxite, because its alumina is comparatively easily available through the Bayer process and large reserves in Surinam bolster the limited quantities known to exist in this country. By comparison, clay as a class has been a leaner and more refractory source of aluminum, and although many methods of extraction have been developed none has achieved commercial success.

Into this situation the war has injected some new considerations that are acting as a powerful stimulant. From the early days of the war it was evident that the element of airpower was to become a crucial and possibly overwhelming factor in battles of the future. As today's combat aircraft is built principally of the light metals a tremendous expansion in aluminum production has taken place, bringing with it an acute realization of the slender supplies of bauxite available within the United States. The point became even clearer as the German submarine campaign along the East coast and in the Caribbean during 1942 made delivery of Surinam bauxite more difficult and costly.

Although a large body of opinion still is doubtful of the commercial prospects of clay as an aluminum ore in the postwar period if it must meet bauxite competition on an equal basis, even the most skeptical are impelled to concede that in the interest of national security the clay processes must be developed to a point that will make the country independent of foreign ore if the need should arise in the future. As to whether this may lead to the creation of a fully developed industry or be limited to small-scale plants sufficient to prove and develop the technique, only the future can reveal. In any case, both private organizations and Government agencies are actively investigating clays. During 1942 the Bureau of Mines conducted extensive clay-drilling programs.

Naturally all groups active in this movement have tended to look first for clays containing a high available alumina content, as they

Digitized by Google

offer the most immediate promise of success. The fire clays of Missouri are most attractive from that standpoint, but they are not sufficiently extensive. The high-alumina clays of Pennsylvania have the advantage of location near high-calcium limestone and coal that would be required if they were to be treated by the lime-soda process. Lower-quality clays, however, are also receiving attention, for they are much more abundant and widely distributed.

At the request of the War Production Board, a committee of the National Academy of Sciences surveyed domestic aluminum sources, and their findings were embodied in a report submitted June 9, 1942.[7] Their investigations led the committee to conclude that although bauxite was the best raw material for producing aluminum, the clays, red muds, and alunite should not be neglected. They found that the acid-process pilot plant operated by the Tennessee Valley Authority was not producing alumina pure enough to be used in the manufacture of aluminum, but they did encourage further progress by offering suggestions as to methods of purification. The following are selected quotations from the report pertaining to clay:

As a matter of insurance in the production of alumina, the War Production Board should consider the construction of lime-soda sintering plants in connection with the Bayer process plants. This would enable each Bayer process plant in the United States to operate on high-silica bauxite and it would also make possible the production of a portion of the alumina, in these combination plants, from clay.

The Committee considers a modified Pedersen process for the production of alumina from clay as the most promising process that will be independent of the Bayer process. This process consists essentially of sintering clay with lime and subsequently leaching with soda. There are many ramifications in the details and in the treatment of the liquors which need test plant study. It is therefore recommended, that the War Production Board allocate to the War Metallurgy Committee a maximum of $100,000 for the construction and operation of a test plant to study the modified Pedersen process for the production of alumina from clay. It is suggested also that the War Production Board facilitate the acquisition of equipment for this test plant. A "Project Priority" is suggested.

It is recommended, that the Aluminum Co. of America be asked to prosecute vigorously pilot plant work on the lime-soda treatment of clay. To facilitate this work, it is suggested that the War Production Board assist the Aluminum Co. of America in obtaining either pilot plant equipment for work on clay or, preferably, a larger pilot plant for the treatment of red mud, thus making available the present pilot plant for work on clay.

It is recommended, that the work now in progress on alumina at the College Park Experiment Station of the Bureau of Mines be continued, and that the War Production Board assist the Bureau in obtaining equipment for this work. A "Project Priority" for this alumina work is suggested.

It is suggested that large quantities of bauxite could be conserved by restricting its use in the manufacture of aluminum sulfate. Calcined kaolin clay apparently can be substituted for the production of aluminum sulfate.

As a means of acquiring a fundamental understanding of the physical structures of the various clays the X-ray and electron microscope are powerful research tools. The progress of the past 15 years is summarized in a report by Grim.[8] Although the electron microscope is still too new to have developed a large body of information on the clays, micrographs have shown that:[9]

The montmorillonites show structures ranging from a fluffy amorphous-appearing material to well-defined, extremely thin plates. Nontronite has flat, frayed

fibers; kaolinite and dickite both have hexagonal plate-shaped crystals, and halloysite has long split rods. Dickite crystals are much thicker than most kaolinitic crystals.

With a view to suggesting a series of the more important tests recognized by the various industries, whereby any given clay can be classified according to its possible uses, a group in the Bureau of Mines working under the supervision of Oliver C. Ralston prepared a syllabus of clay testing that should prove to be very useful.[10]

Foreign trade	1347

GENERAL CONDITIONS

The total value of the products of the natural abrasives industries rose about 9 percent in 1942 compared with 1941. All classes of abrasives shown except tripoli, millstones, garnet, and grindstones made sizable gains in value of products. The value of sales of quartz and of ground sand and sandstone was at a high level; in fact, the value of ground sand and sandstone established a new record. The value of pumice and pumicite sales also was the highest yet recorded. The sales value of tube-mill liners and grinding pebbles in 1942 increased moderately over 1941.

Salient statistics of the abrasives industries in the United States, 1941–42

	1941	1942	Percent of change in 1942
Domestic production (sold or used by producers):			
Natural silica abrasives:			
Diatomite	(1)	(1)	
Tripoli	$421,746	$272,428	−35
Quartz	228,587	331,494	+45
Ground sand and sandstone	3,073,730	3,646,643	+19
Special silica-stone products:			
Grindstones and pulpstones	545,556	539,739	−1
Oilstones and related products	(1)	(1)	
Millstones	15,579	10,391	−33
Flint lining and grinding pebbles	276,042	295,761	+7
Natural silicate abrasives:			
Pumice and pumicite	669,514	706,199	+5
Garnet	371,752	299,904	−19
Natural alumina abrasives:			
Emery	42,484	49,413	+16
Total natural abrasives [2]	[2] 5,644,990	[2] 6,151,972	[2]+9
Total artificial abrasives [3]	16,444,319	23,856,488	+45
Foreign trade:			
Imports	15,470,148	22,696,338	+47
Exports	3,219,642	6,684,352	+108

[1] Bureau of Mines not at liberty to publish figures. Average for diatomite for 1939–41 was $1,915,405.
[2] Excludes value of diatomite and oilstones and related products, which the Bureau of Mines is not at liberty to publish.
[3] Includes material produced in Canada; Bureau of Mines not at liberty to publish United States data separately.

Digitized by Google

Paced by the enormously increased demand for abrasives caused by the war, the production of crude manufactured (artificial) abrasives surpassed all previous records by substantial margins for the third successive year. The combined total output reached by aluminum oxide, silicon carbide, and metallic abrasives in 1942 rose to 370,578 short tons valued at $23,856,488, 33 percent more in tonnage and 45 percent more in value than the figures reported for the former record year (1941). With aluminum oxide and silicon carbide production operating at full capacity and metallic abrasives production at nearly 75 percent of capacity, all three classes of manufactured abrasives for which data are shown achieved record outputs in both quantity and value. The percentages of increase in tonnage in 1942 compared with 1941 were: Silicon carbide, 37 percent; aluminum oxide, 24 percent; and metallic abrasives (steel shot and grit), 45 percent.

The total value of imports of natural abrasive materials into the United States rose to $22,696,338 in 1942, 47 percent greater than in 1941, when the total value reached $15,470,148. In both 1941 and 1942, imports of smaller diamonds ("glaziers' and engravers', unset, and miners' ") into the United States continued at a record-breaking rate, increasing to 6,882,248 carats in 1941 and 11,203,704 carats in 1942, compared with 3,809,071 carats in 1940. Imports of bort in 1942 rose sharply compared with 1941 and were the highest reported since 1937. Imports of corundum ore, which doubled in quantity from 1940 to 1941, declined somewhat in 1942. As in 1941, there were no receipts of emery ore, and pumice imports were very small. The combined value of exports of domestic abrasives and abrasive products in 1942 was twice that in 1941 and higher than in any year since 1920. A very large increase compared with 1941 in the export value of emery and corundum abrasive wheels brought the 1942 total of these products almost to the 1918 figure of $3,862,531. The value of exports of grindstones rose 20 percent, whereas the value of all other natural abrasives, whetstones, hones, etc., dropped slightly.

This chapter includes data for most of the materials used chiefly as abrasives, although certain clays, oxides, and substances mentioned later under "Miscellaneous mineral abrasive materials" are not included in the statistics presented herein. On the other hand, certain of the "abrasive materials" for which figures are included also have important nonabrasive uses.

NATURAL SILICA ABRASIVES

Diatomite.—The Bureau of Mines has not been at liberty to publish annual production data for diatomite since 1926. Total output (sales) for 3-year periods, however, may be shown. Total sales for the three most recent of such periods were as follows—1939–41: 360,502 short tons valued at $5,746,216; 1936–38: 279,645 tons valued at $4,377,353; and 1933–35: 244,342 tons valued at $3,618,428. Sales of diatomite in 1942 were somewhat higher in quantity and value than for 1941.

As in other recent years, California and Oregon were the chief producing States. Other States in which diatomite was produced in 1942 were Florida, Idaho, Nevada, and Washington.

Digitized by Google

About half of the diatomaceous earth marketed in the United States in 1942 was used in filtration, about one-quarter in various types of insulation, another one-sixth as fillers or admixtures, and the remainder for other miscellaneous uses, including small amounts for abrasives.

Prices at the beginning of 1942, according to E&MJ Metal and Mineral Markets, were as follows: Crude dried diatomite f. o. b. mines (Nevada), in bulk, $7, in bags, $12; 40-mesh, $18; 200-mesh, $22.50; low-temperature insulation, $19; and high-temperature, $40. On April 30 and throughout the year, quotations were: Crude dried diatomite f. o. b. mines (Nevada), in bulk, $7 (nominal); 98–100 mesh, $20; low-temperature insulation, $19; high-temperature insulation, $30; fine abrasives, 2 cents a pound (all bags are extra).

Several applications of diatomite were reported in the literature. Its employment as a decolorizing filter aid,[1] the advantages of its use as an ingredient of paint,[2] and in the manufacture of paper,[3] and its utilization in the construction of small homes [4] were described.

A flow sheet giving a simplified description of the mining and processing of diatomite at the operations of the Johns-Manville Products Corporation, Lompoc, Calif., accompanied by photographs of mines and refining plants, was published.[5] Japanese deposits of diatomite and their uses were described during 1942.[6]

Tripoli.—Both the quantity and value of tripoli (including Pennsylvania rottenstone) dropped sharply to 17,536 tons, worth $272,428, the lowest point in tonnage since 1932. This decline was due largely to the lack of output reported in 1942 for Oklahoma and Texas. Production in 1942 was obtained from Arkansas, Illinois, Missouri, and Pennsylvania (rottenstone).

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1938–42

Year	Illinois		Other States [1]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1938	8,141	$117,107	14,047	$211,974	22,188	$329,081
1939	11,134	148,310	22,340	318,070	33,474	466,380
1940	11,521	155,576	18,691	210,993	30,212	366,569

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1940–42, by uses

Use	1940		1941		1942	
	Short tons	Value	Short tons	Value	Short tons	Value
Abrasives	10,279	$119,609	13,407	$198,252	5,447	$85,013
Concrete admixture	1,683	15,895	1,179	15,168	754	8,895
Filler	8,451	113,862	10,020	145,063	8,887	144,055
Oil-well drilling	1,840	16,949	1,925	22,835	(1)	(1)
Other uses [2]	7,959	100,254	2,770	40,428	2,448	34,465
	30,212	366,569	29,301	421,746	17,536	272,428

[1] Included under "Other uses."
[2] 1940: Filter block, foundry facing, and unspecified; 1941: Foundry facing and unspecified; 1942: Foundry facing, drilling mud, and unspecified.

Fillers and abrasives continued to be the largest markets for tripoli in 1942, as in 1941, absorbing 51 and 31 percent of the total sold. Other uses in 1942 were concrete admixture, oil-well drilling, foundry facing, and uses not specified.

Quotations on tripoli, as reported by E&MJ Metal and Mineral Markets, remained unchanged during 1942, as follows (prices per ton, f. o. b. Missouri, in paper-lined burlap bags, minimum carload, 30 tons): Once-ground through 40-mesh, rose or cream colored, $14.50; double-ground through 110-mesh, rose or cream, $16; air-floated through 200-mesh, $26.

Quartz.—The output of crude, crushed, and ground quartz from pegmatite veins or dikes and from quartzite in 1942 rose to 65,878 short tons worth $331,494, a gain of 58 percent in quantity and 45 percent in value compared with 1941. This was the largest tonnage reported since 1918 and the highest value since 1914. Sales of ground quartz in 1942 more than doubled compared with 1941, and sales of crushed material were 90 percent more than in 1941, but quartz sold or used without preparation decreased sharply.

Quartz (crude, crushed, and ground) [1] sold or used by producers in the United States, 1938–42

Year	Crude		Crushed		Ground		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1938	4,493	$17,023	9,930	$27,941	4,188	$43,233	18,611	$88,197
1939	13,739	45,785	15,504	49,186	5,716	58,067	34,959	153,038
1940	3,606	17,099	17,652	58,897	10,607	100,394	31,865	176,390
1941	8,977	39,247	24,101	94,913	8,607	94,427	41,685	228,587
1942	2,043	7,937	45,747	144,808	18,088	178,749	65,878	331,494

[1] To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.

In 1942, output of quartz was reported from 15 States, the same number that produced in 1941; however, no output was reported from Oregon in 1942 and none from Virginia in 1941.

[1] To avoid duplication, the ground material included is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.
[2] Included under "Other States."
[3] 1940: Maryland, New Jersey, New York, Pennsylvania, Tennessee, and Wisconsin; 1941: Maryland, New Hampshire, New York, North Carolina, Tennessee, and Wisconsin; 1942: Arizona, California, Maryland, New York, North Carolina, Tennessee, Virginia, Washington, and Wisconsin.

The production and grinding of "flint"—apparently sugar quartz or vein quartz—by the United Feldspar & Minerals Corporation, Spruce Pine, N. C., for use in sandpaper and abrasives was described.[7] Deposits of quartz and quartzite suitable for commercial development in New Hampshire were described and analyses of quartzites given by Meyers.[8]

Ground sand and sandstone.—Sales of ground sand and sandstone in 1942 rose to 527,886 short tons, only 1 percent less than the record year (1917—532,454 tons) and 8 percent greater than in 1941. The value of sales, however, reached $3,646,643, 205 percent more than in 1917 and 19 percent higher than the former record reported in 1941. Output in all States or groups of States for which comparative totals are shown was substantially higher in 1942 than in 1941, except for Ohio-Virginia-West Virginia, in which production (sales) only slightly exceeded that for 1941. States producing sizable tonnages of ground material were Illinois, New Jersey, Ohio, and Pennsylvania.

Ground sand and sandstone sold or used by producers in the United States, 1938–42

Year	Short tons	Value	Year	Short tons	Value

[1] Included under "Other States."
[2] 1940: Missouri, North Carolina, and Wisconsin; 1941: California, Missouri, and Wisconsin; 1942: Georgia, Missouri, and Wisconsin.

The three chief uses for ground sand and sandstone in 1942 were foundries (34 percent of the total); pottery, porcelain, and tile (26 percent); and abrasives (22 percent). Other important outlets are for fillers and in the glass and enamel trades.

Ground sand and sandstone sold or used by producers in the United States in 1942, by uses

Use	Short tons	Value	
		Total	Average per ton
Abrasive:			
Cleansing and scouring compound	87,317	$507,669	$5.81
Other	28,106	200,905	7.15
Enamel	22,043	141,305	6.41

Other uses	32,778	216,286	6.60
	527,886	3,646,643	6.91

Abrasive sands.—Production of natural sands with a high silica content, employed for sand blasting, scouring stone, grinding glass, sand paper, and other abrasive uses, rose in 1941—the latest year for which data are at present available—to 1,001,814 short tons valued at $1,388,966, compared with 856,309 tons valued at $915,925 in 1940, an increase of 17 percent in tonnage and 52 percent in value. The 1941 total includes 371,049 tons of blast sand valued at $912,626—45 percent more in quantity and 53 percent more in value than that reported in 1940. See chapter on Sand and Gravel for 1942 figures.

SPECIAL SILICA-STONE PRODUCTS

Grindstones and pulpstones.—Total sales of pulpstones and grindstones in 1942 totaled 14,681 short tons valued at $539,739, a decrease of 6 percent in tonnage and a slight decrease in value compared with 1941. In spite of heavy competition from manufactured stones, the tonnage of grindstones sold in 1942 was but 6 percent less than in 1941, and the value only slightly less than in 1941 although consider-

Digitized by Google

ably above that in 1940. Output of natural pulpstones in 1942 decreased about 2 percent in tonnage to 1,918 tons, although the value rose 5 percent to $116,976. Grindstones were quarried in 1942 in Ohio and West Virginia and pulpstones in Washington and West Virginia.

Grindstones and pulpstones sold by producers in the United States, 1938–42

Year	Grindstones		Pulpstones		
			Quantity		Value
	Short tons	Value	Pieces	Equivalent short tons	
1938	4,653	$149,019	417	1,553	$90,987
1939	7,917	257,350	672	2,517	169,025
1940	8,790	284,809	901	4,533	211,639
1941	13,573	434,208	685	1,963	111,348
1942	12,763	422,763	528	1,918	116,976

The production of grindstones by the Constitution Stone Co., Constitution, Ohio, in its quarries and finishing mills in Ohio and West Virginia was described by Random.[9] The circular, rough blocks of stone coming from the quarry weigh up to 5 or 6 tons and may measure 7 feet in diameter, but grindstones completed at the company finishing mills range from 6 to 84 inches in diameter and from 1 to 20 inches in thickness. The stones produced are a medium-coarse, hard grit and are shipped largely to manufacturers of saws, millworking equipment, machine knives, and similar products. Although competition from artificial stones has been severe in recent years, the war has aided in maintaining a fairly active market for the natural product.

The development of pulpstones during the present century was traced by Dupuis.[10] Different patterns of the working face of sandstone and artificial pulpstones were illustrated in a paper-trade journal [11] to suggest methods of obtaining increased grinding surfaces. Characteristics and structure of foreign (Finnish) artificial pulpstones were discussed.[12]

Oilstones and related products.—Sales of natural sharpening stones, including oilstones, whetstones, scythestones, and rubbing stones, were somewhat higher in 1942 than in 1941. The Bureau of Mines, however, is not at liberty to publish the figures. States in which production was made in 1942 and the type of stone reported from each were as follows: Arkansas, oilstones and whetstones; Indiana, scythestones, whetstones, and rubbing stones; New Hampshire, scythestones; and Ohio, scythestones, whetstones, and lathestones.

[2] Bureau of Mines not at liberty to publish figures.

Grinding pebbles and tube-mill liners.—Total sales of grinding pebbles and tube-mill liners in 1942 increased to 18,063 short tons valued at $295,761, a gain of 6 percent in tonnage and 7 percent in value compared with 1941. Of the total for 1942, grinding pebbles totaled 15,487 tons worth $245,794 and tube-mill liners 2,576 tons valued at $49,967. Similar figures for 1941 were: Grinding pebbles, 13,561 tons, $221,826; tube-mill liners, 3,411 tons, $54,216.

In 1942, grinding pebbles or tube-mill liners, or both, were produced in six States—Alabama, California, Minnesota, North Carolina, Texas, and Wisconsin. In Alabama, the Great Lakes Foundry Sand Co., Detroit, Mich., marketed grinding pebbles produced near Elmore. John C. Momand, Carlsbad, Calif., sold small quantities of beach pebbles.

Jasper Stone Co., Sioux City, Iowa, in 1942 continued production and sales of both liners and mechanically rounded pebbles from its Jasper (Minn.) quartzite deposits. The Southern Products & Silica Co., Lilesville, N. C., owned by Charlotte Chemical Laboratories Inc., Charlotte, N. C., and the W. R. Bonsal Co., Hamlet, N. C., produced silica pebbles near Lilesville, N. C. This firm also marketed flint pebbles produced in Texas. Harris Granite Quarries Co., Salisbury, N. C., produced rounded granite cubes and granite liners.

True flint pebbles were shipped from various points in four counties in south central Texas by Philip S. Hoyt, Van Horn, Tex. The Arley Mining Co., Pearsall, Tex., owned by the Richard L. Cawood Co., East Liverpool, Ohio, produced flint pebbles, as did also the

Digitized by Google

Dezendorf Marble Co., Austin, Tex. The Baraboo Quartzite Co., Baraboo, Wis., marketed quartzite pebbles and liners.

Genuine nodular amorphous flint pebbles, of good shape and said to have similar wearing qualities, purity, and the appearance and color of French pebbles, are being marketed by the Richard L. Cawood Co., East Liverpool, Ohio, according to the trade press.[13] The pebbles occur in the so-called Edwards chalk in south central Texas in beds of a red claylike matrix. Some of this matrix remains attached to the pebbles as a thin coating which, for certain uses, must be removed by ball milling. All pebbles, however, are not of equal quality, and many must be discarded.

Grinding mediums and mill liners made of Salisbury granite, quarried near Salisbury, Rowan County, N. C., were described.[14] Sizes of liners and pebbles, with recently quoted prices for each size and degree of preparation, are given. A domestic burrstone lining material has been developed, after careful tests, to replace the product formerly imported from Belgium. The new-type burrstone differs in structure from the Belgian product, does not have soft spots, and withstands impact and abrasion tests satisfactorily.[15]

Quartzite pebbles are abundant in certain areas of southwestern Saskatchewan, according to the Department of Natural Resources of the Province. A reconnaissance survey of three areas in the Province has disclosed large supplies.[16] Careful hand sorting would be necessary, as other rocks of similar size, shape, and color occur with the quartzite. Tests to determine their suitability for use as grinding mediums have been undertaken.

NATURAL SILICATE ABRASIVES

Pumice and pumicite.—Sales of pumice and pumicite in 1942 topped those in the previous record year (1941) by 8 percent in tonnage and 5 percent in value, rising to 126,522 short tons valued at $706,199, compared with 117,310 tons worth $669,514 in 1941.

Output of pumice or pumicite in 1942 was reported from seven States—California, Kansas, Nebraska, New Mexico, Oklahoma, Oregon, and Texas. The leading producing States in 1942 were California, Kansas, New Mexico, and Nebraska.

Pumice and pumicite sold or used by producers in the United States, 1938–42

Year	Short tons	Value	Year	Short tons	Value
1938	65,742	$312,886	1941	117,310	$669,514
1939	89,159	424,780	1942	126,522	706,199
1940	82,407	449,914			

Pumice and pumicite used for abrasive purposes increased 11 percent in 1942 over 1941. Sales or use in concrete admixture and aggregate continued at a high level. Consumption for acoustic

plaster decreased 7 percent in tonnage, although showing a substantial increase in value. The decline in quantity sold or used for acoustic purposes and for concrete may be more apparent than real, however, since two or three firms producing moderate-size tonnages did not report their figures broken down by uses. In the absence of information by means of which estimates as to possible uses might be made, the amounts in question necessarily were placed under "Other uses."

Although volcanic ash is cheap and widely distributed in certain areas, its iron content has greatly restricted its use in ceramic applications.[17] Attempts to remove the iron by various means, including concentration, magnetic separation, and leaching, have been unsuccessful, as the iron is in the form of a complex silicate. Decolorizers, such as selenium and selenium combined with arsenic trioxide, gave promising results. The plasticity, dry strength, and glaze fit of hotel chinaware bodies are improved by substituting substantial quantities of volcanic ash for ball clay and feldspar. Potential applications are the use of volcanic ash as a glaze component and in low-cost glass. Iron oxide, however, usually gives a yellow or ivory tint to the fired ware.

The manufacture of a fire-resistant concrete masonry unit using pumice is described in the trade press.[18] Volcanic ash deposits in Texas, in Grimes County,[19] in Polk and adjoining counties,[20] and in the Rio Grande area,[21] were described. In the last-named study, the chemical and physical compositions of volcanic ash in that area were analyzed. When mixed with plastic clays, the resulting brick is said to be far superior to ordinary brick.

Garnet.—Although sales of garnet reported to the Bureau of Mines in 1942 decreased 21 percent in quantity and 19 percent in value, they were still somewhat above the levels of 1939, and the period 1931 to 1936. (See fig. 2.) The output of garnet produced for sale in 1942

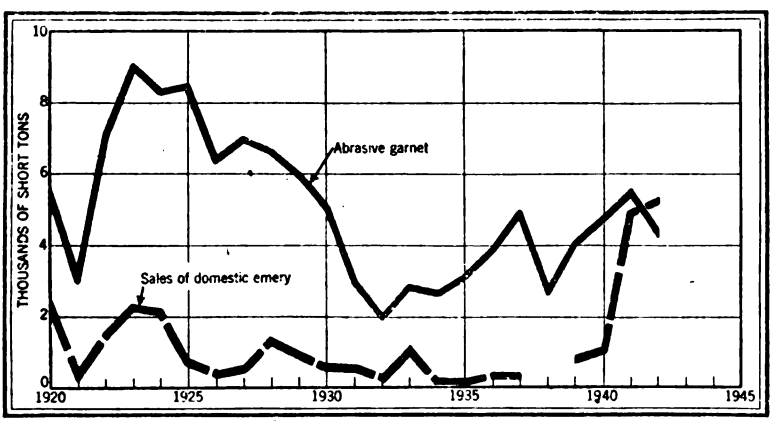

FIGURE 2.—Marketed production of abrasive garnet and domestic emery in the United States, 1920–42.

came from New York, North Carolina, and Idaho. Mas-Celo Mines, Inc., Burnsville, N. C., ceased business in June 1942, and the property remained idle the rest of the year. Yancey Cyanite Co. was to reopen the plant early in 1943. Recovery of garnet concentrates of probable

commercial value from Oregon beach sands was reported by Dasher, Fraas, and Gabriel.[22]

Abrasive garnet sold or used by producers in the United States, 1938–42

Year	Short tons	Value	Year	Short tons	Value
1938	2,669	$191,658	1941	5,501	$371,752
1939	4,056	278,534	1942	4,357	299,904
1940	4,716	259,345			

Garnet prices, as quoted by E&MJ Metal and Mineral Markets, remained constant during 1942, as follows: New Hampshire, f. o. b. mines, per ton, concentrate, $35; grain, $80 to $140; New York Adirondack garnet concentrates, grain, $85; Spanish grades, c. i. f. port of entry, $70 (nominal).

NATURAL ALUMINA ABRASIVES

Corundum.—Practically all of the natural corundum used in this country in recent years has been imported from South Africa, although small receipts from other countries have been reported occasionally. The need of using it for war purposes and the uncertainties of a long ocean haul have led to intensive investigation of known or potential deposits, in order to develop domestic sources of supply if possible. In North Carolina a survey of old producing localities and existing reserves was undertaken at the request of the War Production Board.[23] Deposits in other regions also have been studied.

Emery.—The sales of emery produced in the United States in 1942 rose to 5,277 short tons worth $49,413, an increase of 8 percent in tonnage and 16 percent in value compared with 1941 (see fig. 2). This figure is the highest since 1918, when output (including a small amount of corundum) totaled 10,422 tons. The entire output in 1942 came from the Peekskill (N. Y.) region. Producers reporting shipments were Joe DeLuca, Di Rubbo & Ellis, and Scalzo & Pisano. Floors surfaced with a top coating of graded emery aggregate, portland cement, and water are rendered nonslippery, even when wet, give good traction, and have increased load-bearing properties and high resistance to wear.[24]

Emery sold or used by producers in the United States, 1938–42

Digitized by Google

accuracy and higher working speeds, have enlarged the scope of usefulness of diamonds. For many years diamonds have been essential in glass cutting and in rock drilling. Diamonds and diamond dust embedded in various matrices, such as powdered metal, plastics, and ceramic bonds, used in almost all manufacturing processes, are now much more important, quantitatively. In addition to their abrasive uses, diamonds are vitally needed because of their abrasion-resistant qualities, which make them especially suitable for use as dies in drawing copper, tungsten, brass, and other wires or filaments and as atomizers in oil-burning equipment.

Although there have been reports in the trade press of the possible reopening of the long idle Arkansas diamond properties,[26] by far the chief sources of abrasive or industrial diamonds now are Brazil and Belgian Congo. Other areas in Africa and South America also produce significant quantities of industrial diamonds. Imports of diamond dust into the United States in 1942 declined in value. Imports of bort increased over fourfold but were considerably under the 1937 figure. Diamonds for industrial use ("glaziers' and engravers', unset, and miners' diamonds") rose to 6,882,248 carats in 1941 and 11,203,704 carats in 1942 compared with 3,809,071 in 1940, a 194 percent increase within only 2 years. The average value per carat continued to decline, reflecting the greater use of smaller stones. The average values for 1942 and the 2 previous years were: 1942, $1.98; 1941, $2.17; and 1940, $2.89.

The world production of diamonds in 1942 probably approximated that of 1941, when slightly less than 9,350,000 carats were produced. The 1941 figure was over one-third (34 percent) less than in 1940, when production reached 14,250,000 carats. In normal years about two-thirds of the annual world production of diamonds consists of industrial stones, although their value scarcely exceeds one-fifth of the total annual diamond output. Unlike gem diamonds, industrial diamonds are actually consumed. In normal times, over half the diamonds used in industry were destroyed after 12 months' continuous employment.[27] Today the average life of industrial diamonds should be shorter, owing to the present intensity of work and the hardness of the alloys used for armament purposes.

The largest producing areas are in Africa—Belgian Congo, Gold Coast, Sierra Leone, and Angola together supplied 94 percent, by weight, of the total world output in 1941; South Africa and South-West Africa only 2 percent; and South America (Brazil, Venezuela, and British Guiana) 4 percent.[28] Of the 94 percent produced in Equatorial Africa, the output of the Gold Coast, Sierra Leone, and Angola represented 11, 9, and 8 percent of the world production.[29] Most of the Belgian Congo output came from the famous Beceka mines. Sinclair[30] described mining and market conditions leading to the shut-down of the large South African diamond mines and the possible effect of the heavy demand for stones of industrial grade.

A new source of alluvial diamonds in the Ural Mountain region, U. S. S. R., was noted.[31]

Total sales of diamonds in 1942, according to market estimates, reached nearly £10,000,000 compared with £7,000,000 in 1941 and nearly £4,050,000 in 1938.[32] A considerable shift in the relative positions of gem and industrial diamonds has occurred in the last year or two. Gem sales have been smaller but prices much higher than heretofore. The prices of industrial diamonds, however, by agreement, have remained unchanged since the start of the war. Indications therefore point to an appreciable advance in the sale of industrial stones.[33] Factors in this increased importance of working diamonds, as above noted, are the volume and speed of war production, the greater hardness of armament alloys, with its attendant increase in replacement requirements, and the rapidly expanding range of its usefulness.[34]

A group of papers covering changes and progress in the diamond industry during 1942 was published in the early part of 1943.[35] World output, which is concentrated largely in the United Nations countries, and stocks were discussed by Ball.[36] After the Low Countries were invaded, the diamond-cutting industry was widely dispersed. Cutting industries have been established in Transvaal, Palestine, Brazil, Cuba, Puerto Rico, Great Britain, and the United States. Many gem-cutting establishments also have been producing specially shaped diamonds for tools or other industrial use.[37] Photomicrographic studies and the use of specially designed machines have resulted in marked improvements in the technique and speed of making drilling dies. Although the present facilities for die drilling in the United States only about equal minimum requirements, expansion to provide for increased demand is under way.[38] Wheel-dressing tools use more of the larger diamonds, but diamond core drilling consumes the larger portion of the smaller sizes, although the use of smaller stones in a cast or sintered head for dressing tools is increasing.[39] The grinding of hard and brittle metals, nonmetals, and synthetics with bonded diamond products has increased enormously in 1942 compared with 1941. Research has resulted in improvements in the composition of metal bonds and in manufacturing processes and in the introduction of a new bond of the ceramic vitrified type with a high glass content.[40]

Excellent summaries of the many industrial applications of diamonds and diamond tools appeared in the Mining Journal[41] and in

Foreign Commerce Weekly.[42] The latter also presented a brief description of localities, production, history, and uses of South American diamonds, especially the Brazilian product. The usefulness of the diamond in the mechanical engineering field was discussed.[43] The experience of a large manufacturing plant in standardizing its diamond tools was published.[44] Information as to shapes and sizes of diamonds suited for truing and dressing purposes and methods of mounting diamonds individually and in diamond-impregnated tools were presented by Larson.[45] In order to cope with the expanding requirements for wheel-dressing tools, a more efficient method of setting the cutting edge was developed, making use of a vacuum for "positioning" the diamond.[46]

Padowicz [47] discussed the factors affecting die requirements and die performance in drawing copper wire at a large wire-drawing mill. Diamond failure was due not so much to wear as to breakage and chipping, caused by various strains having a possible correlation, in certain cases, to the angle of the drilling axis. Preparation, drilling, polishing, and mounting of diamond dies for use in wire drawing were described by Dudding, Eden, and Leeds.[48] Patent history with respect to the invention of the rock drill and notes regarding the early use of diamonds for drilling purposes were presented by Grodzinski.[49]

ARTIFICIAL ABRASIVES

Stimulated by the enormous activity in the munitions, shipbuilding, airplane, and other industries making war materials, the output of manufactured (artificial) abrasives in 1942 surpassed the former peak year (1941) by 33 percent in tonnage and 45 percent in value. Records also were established individually by all three classes of abrasives included in the Bureau of Mines figures. As in 1941, plants making crude aluminum oxide and silicon carbide in the United States and Canada operated at full capacity in 1942 and produced 61,681 short tons of silicon carbide valued at $4,904,309 and 183,633 tons of aluminum oxide valued at $12,719,337—an increase of 37 percent in tonnage of silicon carbide and 24 percent in tonnage of aluminum oxide. Operating at 72 percent of capacity, manufacturers of metallic abrasives (steel shot and grit) increased their sales in 1942 to 125,264 tons valued at $6,232,842, a gain of 45 percent in quantity and 54 percent in value.

[1] Bureau of Mines not at liberty to publish data for United States separately.
[2] Production; includes material used for refractories and other nonabrasive uses.

Production of silicon carbide and aluminum oxide is concentrated largely in the Niagara Falls region of Canada and the United States; some output of aluminum oxide comes from Quebec, Canada, and Alabama. "White High Purity or Special" aluminum oxide produced in 1942 totaled 31,665 short tons valued at $4,509,486, compared with 22,659 tons valued at $2,676,753 in 1941, an increase of 40 percent in tonnage and 52 percent in dollars. Estimated percentage of total consumption of silicon carbide for nonabrasive or refractory purposes in 1942 rose to 35 percent, compared with 32 percent in 1941 and 1940 and 29 percent in 1939. Similar percentages for aluminum oxide were 3 percent in 1942 and 1941, 2 percent in 1940, and 4 percent in 1939.

Metallic abrasives, including steel grit and shot but excluding steel wool, are manufactured in Michigan, New Hampshire, Ohio, and Pennsylvania. An illustrated article describing the plant and manufacturing process of the Harrison Abrasive Corporation, Manchester, N. H., appeared in 1942.[50] A flowing stream of molten steel is broken up by jets of steam. The resulting globules and irrregular particles fall into water, which chills and hardens them. The shot are graded into 16 commercial sizes, and the irregular pieces are crushed and screened into 12 sizes and marked as grit. The material is sold largely for cleaning castings and working stone.

The properties and uses of silicon carbide, aluminum oxide, and boron carbide and particularly their application and employment in the various types of grinding wheels were described in a report printed during 1942.[51] Manufactured abrasives and their utilization in grinding wheels also were discussed by Arend.[52] A description was given of the preparation of crude abrasive aluminum oxide ore received at the manufacturing plant of the Abrasive Co., Philadelphia, Pa., from its electric furnaces in Canada, beginning with the crushing and pulverizing operations through magnetic separation and elaborate grading to the manufacture of the principal end product (abrasive

wheels) by controlled firing schedules.[53] About 75 percent of the firm's business is in aluminous oxide products and the remainder in abrasives made of silicon carbide, which is received at the Philadelphia mill in the form of grain.

MISCELLANEOUS MINERAL ABRASIVE MATERIALS

In addition to the natural and manufactured abrasive materials discussed, many other mineral substances have abrasive uses. Various oxides, including tin oxide, rouge, crocus, chromium oxide, magnesium oxide, and manganese oxide, are utilized as polishing agents. Finely ground as well as calcined clays, high-grade lime, talc, river silt, slate flour, whiting, feldspar, and other substances also are used as abrasives.

FOREIGN TRADE[54]

Imports of corundum ore in 1941 reached 5,865 short tons, slightly over double the 1940 imports and the highest figure at least since 1924. (Before 1924 imports of corundum and emery ore were not shown separately in Mineral Resources volumes.) Imports in 1942, however, declined 19 percent to 4,739 tons. As in 1941, no emery ore was received, and receipts of pumice were at an extremely low level. Imports of "flint, flints, and flint stones, unground," in 1942 were about one-quarter of those received in 1941. Imports of bort increased sharply. Imports of smaller diamonds, comprizing "glaziers' and engravers', unset, and miners' diamonds," totaled 11,203,704 carats valued at $22,154,076 in 1942, compared with 6,882,248 carats valued at $14,908,809 in 1941. The imports in both years were greatly in excess of those in the industrially active years 1940 and 1939. The influence of the expanded war production, as well as the ever-widening utilization of diamonds in industry, contributed largely to this indicated increased consumption.

The value of exports of natural abrasive materials in 1942 totaled $6,684,352, the highest year since 1920. The value of grindstones exported in 1942 rose 20 percent over 1941 to $224,998. The chief increase in value of exports, however, was in emery or corundum abrasive wheels, which were higher in 1942 than in any year since 1918. The value of exports of all other natural abrasives and abrasive products in 1942, though more than double that of 1939 and 1940, declined slightly from the 1941 value.

GENERAL SUMMARY

For the sulfur industry, 1942 was a year of activity and readjustment to meet wartime demands. Except for Great Britain, which still depends largely on imports, the major belligerents enjoyed adequate supplies of sulfur and its primary compounds derived either from natural deposits or recovered as industrial byproducts. Many countries, especially those in isolated or exposed positions like New Zealand, Turkey, and Sweden, began to feel a shortage as their stock piles became depleted and imports were reduced by blockade or deficiency of shipping facilities.

Almost everywhere realization of the crucial role being played by sulfur in industry led to the adoption of policies aimed at achieving national self-sufficiency. Production from local deposits or from previously untapped byproduct sources was encouraged by high prices or subsidies.

As most of the output of the United States sulfur industry is marketed in North America, the decline in export activity was not a serious factor. On the other hand, Italian and Spanish producers, being largely dependent on foreign markets, found that they had lost free access to many of their usual customers, and fully compensating demand did not develop in Europe. Activity was stimulated among the smaller producers, like Chile, Bolivia, Australia, and Canada, which are conveniently located to supply the neglected markets.

In the United States, as in many other countries, new production and consumption records were attained. Mine shipments were not as high as in 1941, owing principally to completion of stock-piling programs. Although sulfur production capacity was ample and stock piles adequate for at least 1½ years' consumption requirements were above ground, conditions in the industry were observed closely by various Government agencies. Transportation was an outstanding

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

problem. Price structures along the East coast were based upon low-cost coastwise water delivery of crude sulfur. With the advent of submarine attacks and requisitioning of ships for other service, sulfur was largely diverted to more expensive railroad and barge routes. Sufficient equipment was available in 1942 to carry sulfur and its

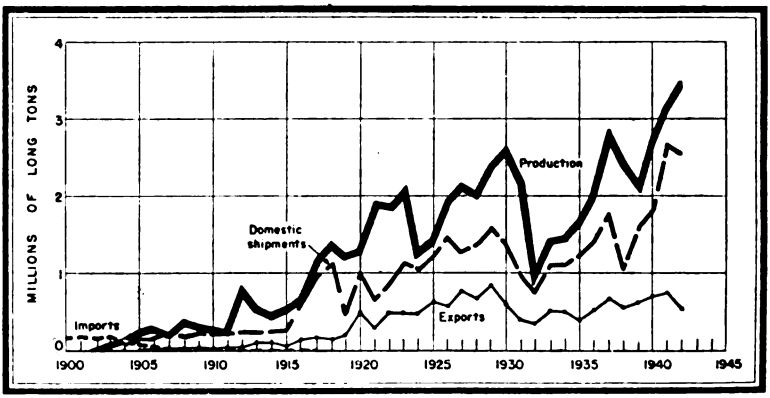

FIGURE 1.—Domestic production, shipments for domestic consumption, exports, and imports of crude sulfur, 1900-1942.

compounds, but some concern was expressed as the tonnage of acids increased. On December 5, 1942, the War Production Board placed sulfuric acid under allocation to permit prompt action in case of emergency and to assure supplies for explosives requirements. Sulfur consumers were urged to maintain large stocks as insurance against future transportation bottlenecks. Prices of sulfur and its compounds remained substantially stable during the year.

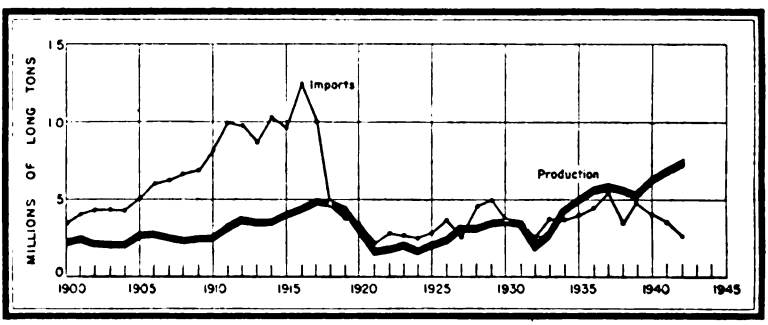

FIGURE 2.—Domestic production and imports of pyrites, 1900-1942.

On June 26, 1942, an indictment charging a violation of the anti-trust laws in the manufacture, distribution, and sale of sulfuric acid was returned against 15 companies and 37 individuals. However, upon the representation of the Secretaries of War and Navy that trial of the case would interfere with the war program, the Attorney General requested its postponement until after the war. The defendants agreed to this.[2]

[1] Less than 1 ton. [2] Revised figures.

SULFUR

DOMESTIC PRODUCTION

Production of crude sulfur in the United States in 1942 attained a new record of 3,460,686 long tons, exceeding the previous high, established in 1941, by 10 percent. Mine shipments, adversely influenced by export restrictions and completion or modification of domestic stock-piling programs, were 8 percent lower than in 1941. Approximately 1,600 long tons of sulfur-bearing ore, containing 10 to 50 percent sulfur, mined in Colorado and Texas for agricultural purposes, are not included in the sulfur total.

REVIEW BY STATES

More than 83 percent of the native sulfur mined in the United States in 1942 came from deposits in Texas and over 16 percent from Louisiana. The remaining fraction of 1 percent was supplied by mines in California and Utah.

Sulfur produced and shipped in the United States, 1938–42

Year	Produced (long tons)				Shipped	
	Texas	Louisiana	Other States [1]	Total	Long tons	Approximate value
1938	2,060,845	328,405	4,158	2,393,408	1,628,847	$27,300,000
1939	1,665,400	422,600	2,979	2,090,979	2,233,817	35,500,000
1940	2,212,839	512,935	6,314	2,732,088	2,558,742	40,960,000
1941	2,596,731	533,620	8,902	3,139,253	3,401,410	54,400,000
1942	2,885,621	570,345	4,720	3,460,686	3,128,559	50,100,000

Digitized by Google

California.—Pacific Sulphur Co. produced sulfur from the Crater claims at Bigpine, Inyo County.

Louisiana.—Freeport Sulphur Co. supplied the entire Louisiana output from Grande Ecaille, Plaquemines Parish. Production from this dome continued to increase steadily.

Texas.—As indicated in the following table (compiled from information issued by the Texas State Comptroller's Office), four organizations produced practically all the Texas output. Duval Texas Sulphur Co. reported production from Orchard Dome, Fort Bend County; Freeport Sulphur Co. from Hoskins Mound and Jefferson Lake Sulphur Co., Inc., from Clemens Dome, both in Brazoria County; and Texas Gulf Sulphur Co., from Boling Dome, Wharton County. The Pecos Orla Sulphur Co. mined sulfur ore at the Michigan claims in Culberson County.

Sulfur produced in Texas in 1942, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co	545,313	592,191	564,850	471,028	2,173,382
Freeport Sulphur Co	118,350	115,280	113,815	97,055	444,500
Jefferson Lake Sulphur Co., Inc	13,096	8,575	21,695	33,218	76,584
Duval Texas Sulphur Co	48,820	58,660	39,305	44,088	190,873
	725,579	774,706	739,665	645,389	[1] 2,885,339

[1] Total differs slightly from Texas production figure in preceding table because certain reports to Texas Comptroller are closed for year on December 25, whereas Bureau of Mines total covers calendar year.

Utah.—Pacific Sulphur Co. produced sulfur in Beaver County.

RECOVERY AS BYPRODUCT

The treatment of copper and zinc ores yields large quantities of sulfur, which are recovered at the mills as pyrites concentrates or at the smelters as sulfuric acid or elemental sulfur. The production of pyrites concentrate is discussed in the Pyrites section of this chapter. In smelting copper and zinc concentrates, sulfur is driven off as a constituent of gases, principally sulfur dioxide, which are used in the manufacture of sulfuric acid at many smelters. The equivalent of about 190,000 long tons of sulfur was recovered as sulfuric acid annually from this source during the 5 years ended in 1942. Such sulfur is not included in the sulfur-production figures for the United States, but the following table shows the output of byproduct acid at both copper- and zinc-smelting plants.

Byproduct sulfuric acid [1] (expressed as 60° B.) produced at copper and zinc plants in the United States, 1938–42, in short tons

	1938	1939	1940	1941	1942
Copper plants [1]	220,297	249,569	254,025	243,812	265,522
Zinc plants	466,879	528,872	586,912	672,177	695,242
	687,176	778,441	840,937	915,989	960,764

[1] Includes small quantity of sulfuric acid produced as byproduct in roasting of high-sulfide gold and silver concentrates.

The recovery of sulfur or sulfur compounds from coke-oven, refinery-still, natural, and other fuel gases is receiving increasing attention. In many foreign countries these processes are encouraged as a step

Digitized by Google

toward self-sufficiency and in the United States as a means of profitably utilizing a waste product or of conserving natural resources. Exemplifying this activity, a description was published in 1942 of progress in attempts to extract elemental sulfur from the enormous reserves of sour natural gas available in southwest Arkansas; here, removal of the sulfur has the additional advantage of greatly improving the quality and value of the fuel gas itself.[3]

Most of the elemental sulfur recovered from gas purification comes from operations using the Thylox process; relatively small quantities are recovered with the Ferrox and Nickel processes. Production in 1942 (reduced to 100 percent sulfur) totaled 5,125 long tons; 4,520 tons valued at $168,333 were shipped. Output came from Illinois, Maryland, Massachusetts, Missouri, New Jersey, New York, Washington, West Virginia, and Wisconsin; Massachusetts and New York were the largest producers. The product was marketed as a paste containing 37 to 50 percent sulfur or as dried relatively pure sulfur. The fine particle size of this material makes it valuable as a fungicide and insecticide, and these uses absorb most of it. Of the 1942 shipments (reduced to 100 percent sulfur), 37 percent was in the form of paste, and the remainder was dried sulfur.

Sulfur is also removed from fuel gases in the form of hydrogen sulfide, most of which is either converted into sulfuric acid or burned as fuel. The hydrogen sulfide recovered in 1942 came from plants using the phenolate, phosphate, and Girbotol processes. In 1942 the recovery of hydrogen sulfide (largely for sulfuric acid manufacture) was equivalent to 19,097 long tons of sulfur; the plants were in California, New Jersey, and Pennsylvania.

The figures covering the byproduct yield of sulfur from gas purification are not included in the sulfur production figures for the United States.

STOCKS

Stocks of crude sulfur held at the mines increased during the year and on December 31 amounted to 4,300,000 long tons. In addition, the producing companies hold substantial tonnages at other locations or in transit. The combined total of all producer-owned stocks at the end of the year was about 5,114,000 long tons, 9 percent more than on December 31, 1941. Although exactly comparable figures are not available for past years, it is apparent that producers' stocks are at or near an all-time high.

PRICE

Crude sulfur was quoted by trade journals at $16.00 per long ton f. o. b. mines throughout 1942. On May 11 (announced April 28) the Office of Price Administration froze prices at the maximum levels of March 1942. Subsequently there were intermittent reports of efforts to both raise and lower prices, but no change was authorized. Refined-sulfur prices, reflecting increased freight costs, were raised approximately 10 percent by some manufacturers before the General Maximum Price Regulation was established, but little or no change took place thereafter.

Sulfuric acid, 66° B., was quoted by journals at $16.50 per short ton at works in tank cars. The General Maximum Price Regulation

[3] Lee, James A., Sulphur from Arkansas Sour Gas: Chem. and Met. Eng., vol. 49, No. 6, June 1942, p. 80.

Digitized by Google

established ceiling prices, which were not disturbed. However, some acid producers were able to increase their over-all realization somewhat by bringing some of their lower-priced sales closer to the standard ceiling.[4]

CONSUMPTION AND USES

The apparent domestic consumption of sulfur in 1942 increased 6 percent over 1941, attaining a new record. This figure may be slightly low, as it does not allow for stock piles accumulated by consumers during 1941.

The following table shows the apparent domestic consumption of sulfur during the past 5 years.

Apparent consumption of sulfur in the United States, 1938–42, in long tons

	1938	1939	1940	1941	1942
Shipments [1]	1,628,847	2,233,817	2,558,742	3,076,038	3,032,043
Imports	2,603	13,976	27,845	28,631	26,018
	1,631,450	2,247,793	2,586,587	3,104,669	3,058,061
Exports:					
Crude	579,107	627,819	746,468	729,464	568,499
Refined	12,707	25,005	19,745	31,312	17,030
	591,814	652,824	766,213	760,776	585,529
Apparent consumption	1,039,636	1,594,969	1,820,374	2,343,893	2,472,532

[1] 1938-40: Mine shipments; 1941-42: Apparent shipments to consumers.

The pattern of industrial sulfur consumption has been estimated by Chemical and Metallurgical Engineering as follows:

Sulfur consumed in the United States, 1938–42, by uses, in long tons [1]

Use	1938 [1]	1939	1940	1941	1942
Chemicals	484,000	695,000	800,000	[2] 1,060,000	[2] 1,570,000
Fertilizer and insecticides	220,000	370,000	410,000	450,000	500,000
Pulp and paper	174,000	240,000	320,000	360,000	365,000
Explosives	50,000	64,000	74,000	[2] 83,000	[2] 90,000
Dyes and coal-tar products	40,000	46,000	51,000	65,000	60,000
Rubber	29,000	43,000	47,000	55,000	35,000
Paint and varnish	50,000	49,000	54,000	65,000	70,000
Food products	5,500	6,000	6,000	6,000	6,000
Miscellaneous	47,500	82,000	86,000	95,000	120,000
	1,100,000	1,595,000	1,848,000	2,239,000	2,816,000

[1] Figures for 1938 not truly representative of consumption but rather of shipments to these specified industries. Consumers carried over large stocks from 1937, therefore consumption in 1938 was larger than total shown.

[2] To avoid disclosing estimated consumption of sulfur in direct defense applications, such as military explosives, sulfur so used in 1941 and 1942 is included under "Chemicals."

Under recent peacetime conditions approximately 70 percent [5] of the brimstone consumed in the United States was converted into sulfuric acid, and the wartime demands of the explosives and petroleum industries have probably increased the proportion. Production of sulfuric acid, calculated as 50° B., is estimated to have increased to 12,520,000 short tons in 1942, 14 percent above the 1941 output of 10,944,000 tons.[6]

Digitized by Google

Chemical and Metallurgical Engineering has estimated the consumption of sulfuric acid, by industries, from 1938 through 1942 as follows:

Sulfuric acid (expressed as 60° B.) consumed in the United States, 1938–42, by industries, in short tons

Industry	1938	1939	1940	1941	1942
Fertilizer	1,900,000	1,970,000	2,260,000	2,500,000	2,950,000
Petroleum refining	1,100,000	1,210,000	1,260,000	1,400,000	1,650,000
Chemicals	800,000	975,000	1,120,000	[1] 1,790,000	[1] 2,250,000
Coal products	585,000	740,000	900,000	940,000	970,000
Iron and steel	590,000	980,000	1,300,000	1,500,000	1,600,000
Other metallurgical	350,000	570,000	640,000	800,000	840,000
Paints and pigments	430,000	520,000	580,000	700,000	760,000
Explosives	140,000	160,000	170,000	[1] 190,000	[1] 195,000
Rayon and cellulose film	320,000	405,000	470,000	555,000	625,000
Textiles	90,000	116,000	125,000	165,000	145,000
Miscellaneous	355,000	384,000	360,000	500,000	530,000
	6,660,000	8,030,000	9,185,000	11,040,000	12,515,000

[1] To avoid disclosing estimated consumption of acid in direct defense applications, such as military explosives, acid so used in 1941 and 1942 is included under "Chemicals."

It is estimated that industry as a whole used 13 percent more sulfuric acid in 1942 than in 1941. The largest increases in consumption were made in the petroleum, fertilizer, and chemical (which includes military explosives) industries—18, 18, and 26 percent, respectively. With the exception of textiles, which decreased 12 percent, other industries enjoyed modest increases of 3 to 12 percent.

Two of the more significant applications of sulfuric acid during this wartime period are in the production of aviation gasoline by the alkylation process and in military explosives. Large expansion programs in these fields are making themselves felt both as volume consumers of strong acids and as producers of spent acids. Each locality has its individual spent-acid problems, which must be solved by regeneration, consumption in some intraplant operation in which weaker acids are satisfactory, or sale to other less critical industries. Whatever the solution, readjustments in the normal handling and distribution of acids are required. Local consumption or regeneration of spent acid was advocated as a means of alleviating the steadily growing demands on railroad facilities. Rail shipments of sulfuric acid have more than doubled during the past 2 years.

The versatility of sulfur in war is illustrated by the practice of stimulating the flow of gum from southern turpentine pines by painting the tap wounds with sulfuric acid.

That sulfur continued to occupy a prominent position in research laboratories is indicated by its use in synthetic rubber, and in less publicized discoveries, such as the compound tetraethyl thiuram monosulfide (a preventive of a serious poultry disease).[7]

FOREIGN TRADE

As a result of the stringent shipping situation, exports of crude and treated sulfur were, respectively, 22 and 46 percent lower than in 1941. The accompanying table of exports by countries reveals the changes in pattern of distribution caused by the war.

[7] Science News Letter, vol. 42, No. 5, August 1, 1942, p. 72.

Digitized by Google

Imports of elemental sulfur (principally from Canada) decreased 10 percent. Imports of sulfuric acid (also largely from Canada) totaled 13,689 short tons and exports 9,679 short tons.

[1] Less than 1 ton.

WORLD PRODUCTION

Censorship restrictions of the belligerent nations have for several years eliminated publication of their production statistics, making any estimate very arbitrary. Available figures are shown in the following table. Judging from the meager information at hand, world production of elemental sulfur probably exceeded 4,300,000 long tons in 1942.

World production of native sulfur, 1937–42, by countries, in long tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1937	1938	1939	1940	1941	1942
Bolivia (exports)	1,712	1,632	2,126	4,065	2,315	3,535

[1] Native sulfur believed to be produced also in Argentina, China, Cuba, India, Iran, Taiwan, and U. S. S. R., but quantity unknown.
[2] In addition, 1,050 tons of sulfur rock (40–80 percent sulfur) reported for 1937.
[3] Data not available.
[4] In addition, following quantities of sulfur rock reported—1937: 19,793 tons; 1938: 16,545 tons. Similar data not available for later years.
[5] Estimated sulfur content of ore, excluding sulfur made from pyrites.

Bolivia.—Active demand and high prices are stimulating expansion of both Concepción and San Pablo de Napa, the latter being the principal Bolivian producer.[8]

Canada.—Substantial quantities of byproduct elemental sulfur were produced for domestic consumption and export; 25,071 long tons were exported to the United States.

Chile.—Surface deposits of sulfur occur along the Andes from the Peruvian frontier to about 36° south latitude. The principal mines

[8] Engineering and Mining Journal, vol. 143, No. 7, July 1942, p. 100.

Digitized by Google

are around Mount Tacora in Arica and in Antofagasta Province near the Bolivian border.[9] Wartime shipping restrictions put Chile's sulfur industry in a good competitive position in the Argentine, Uruguayan, and Brazilian markets, even at high prices. Old operations were active, and the Corporación de Fomento granted capital to open a new deposit in Arica.[10] Although the present situation is satisfactory, the industry is still not particularly profitable, and it is realized that the postwar outlook depends on the development of a more efficient method of treating these ores. The problem is complicated by the fact that these operations, in barren terrain 13,000 to 19,000 feet above sea level, depend on a local resinous moss for fuel.[11] Destructive harvesting is seriously threatening the supply. As coal would have to be brought, at considerable expense, by steamer, rail, and pack horse from south central Chile, the situation is causing some concern. Chilean authorities are sponsoring less destructive methods of harvesting and a program to determine whether or not the plant can be domesticated and cultivated.

Germany.—Although Sicily's sulfur supplies were available to Germany in 1942, the somewhat meager information obtainable indicates it was not necessary to draw heavily on the Italian deposits. Germany's sulfur needs were apparently satisfied by its well-developed byproduct installations and plants using pyrites or calcium sulfate as a raw material. The literature indicates that German technology reported progress in developing efficient sulfur burners and processes that recover sulfur from very low concentrations in coke-oven and coal-distillation gases.[12]

Great Britain.—A committee of the Institution of Gas Engineers recommended three processes—the active-carbon, the oil-washing, and the catalytic—for removing sulfur from coal gas. The active-carbon and oil-washing processes are now in use at 25 plants and the catalytic at 1 plant. Sulfur supplies were conserved by licensing consumers.[13]

Italy.—Conflicting reports obscure the Italian sulfur situation. On the one hand, it has been said that production in 1940–41 was 7 percent less than in the previous year and that labor and equipment shortages, transportation problems, and loss of export markets have seriously restricted the industry. On the other hand, it is stated that the financial situation of producers was satisfactory and no Government subsidies were required; that 200,000 men are now employed compared with 80,000 in 1938–40; and that all requirements were satisfied without diminishing existing stocks.[14] Evidence of some difficulties is found in the organization of a joint German-Italian company, Societa per Incremento Produzione Zolfi, whose stated purpose is to deal with the problems of high costs and lost markets by pooling inventions and introducing a more efficient process.

Japan.—Although exact information is lacking for 1942, it is known that native sulfur deposits in Japan make it self-sufficient in this commodity.

Mexico.—At present the only sulfur produced in Mexico is a very impure material from the State of San Luis Potosí. A new carbon disulfide plant will use it as a raw material.

New Zealand.—Consideration was given to opening deposits in the Hot Lakes district, and research agencies studied the concentration problems involved.

Palestine.—In the Gaza Area a sulfur deposit estimated at 1 million tons has been reported.[15]

Spain.—The European press reported that Sociedad Española de Construccion Electromecanica is to operate a new plant capable of producing 50,000 tons of sulfur and 15,000 tons of sulfuric acid annually.

Sweden.—Sulfur is a byproduct of the Swedish Navy's new shale-oil plant at Kinnekulle. Sulfur supplies are under strict allocation.[16]

U. S. S. R.—Reports continue to appear of the discovery of huge supplies of native sulfur, comparable with the Sicilian deposits, in the Turkmen S. S. R. east of the Caspian Sea.

PYRITES

DOMESTIC PRODUCTION

In 1942, for the third successive year, a new record was attained in production of pyrites in the United States—12 percent higher than the 1941 total. Ninety-eight percent of the output was classified as fines, largely flotation concentrates, and the remainder as lump.

Pyrites (ores and concentrates) produced in the United States, 1938–42

Year	Quantity		Value	Year	Quantity		Value
	Gross weight (long tons)	Sulfur content (percent)			Gross weight (long tons)	Sulfur content (percent)	
1938	555,629	39.4	$1,685,766	1941 [1]	645,257	41.9	$2,009,000
1939	519,497	42.3	1,560,000	1942	720,363	42.6	2,464,000
1940	626,640	41.8	1,920,000				

[1] Revised figures.

In 1942, 492,720 long tons were consumed by the producing companies and 234,639 tons were sold compared with 443,983 and 207,504 tons, respectively, in 1941.

REVIEW BY STATES

California.—The Mountain Copper Co. produced pyrites in California in 1942; output came from the Hornet mine in Shasta County.

Colorado.—Four companies reported a total production of 11,067 long tons in 1942. They were Minnesota Mines, Inc., Clear Creek County; Rico Argentine Mining Co., Dolores County; and John Hamm Mining & Milling, Ltd., and Resurrection Mining Co., Lake County.

Illinois.—From its coal-cleaning plant in Henry County, the Midland Electric Coal Corporation produced 13,562 long tons of pyrite (coal brasses) in 1942.

Indiana.—The Snow Hill Coal Corporation produced pyrite (coal brasses) at its Talleydale mine in Vigo County in 1942.

Montana.—The pyrites produced in Montana in 1942 came from the Anaconda Copper Mining Co. at Anaconda, where it is recovered as a flotation concentrate in copper-plant operations.

New York.—In 1942 New York produced 68,826 tons of pyrites.

[15] Chemical Age, vol. 47, No. 1205, August 1, 1942, p. 105.
[16] Foreign Commerce Weekly, vol. 8, No. 6, August 8, 1942, p. 28.

Digitized by Google

Pennsylvania.—The Bethlehem Steel Co. produced pyrite concentrates in Lebanon County.

Tennessee.—The Tennessee Copper Co. operations in Ducktown Basin, Polk County, made Tennessee the largest producer of pyrites in 1942. None of this material, a flotation concentrate, appeared on the market, as all of it was consumed by the producing company.

Virginia.—The General Chemical Co. produced a substantial tonnage of pyrites at the Gossan mine in Carroll County and consumed the entire output in its own manufacturing operations.

Wisconsin.—The one company reporting production of pyrites in Wisconsin in 1942 was the Vinegar Hill Zinc Co., Grant County. The company sulfuric acid plant consumed the entire output.

FOREIGN TRADE

Compared with 1941, imports of pyrites decreased 19 percent in 1942, largely owing to an 87-percent drop in tonnage from Spain. Increased Canadian shipments, which now occupy the position in the United States market formerly held by Spanish, partly counteracted the loss. Canada furnished 94 percent of the imports in 1942.

Although little or none was available, Spanish pyrites, guaranteed 48 percent sulfur, was quoted nominally at 12 cents per long-ton unit of sulfur, c. i. f. United States ports.

Pyrites, containing more than 25 percent sulfur, imported into the United States, 1938–42, by countries

Country	1938		1939		1940		1941		1942

WORLD PRODUCTION

Although little or no precise statistical information is available for the wartime period, world production of pyrites in 1942 probably approximated 9 million metric tons containing about 3,900,000 tons of sulfur.

World production of pyrites (including cupreous pyrites), 1938, 1941, and 1942, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1938		1941		1942	
	Gross weight	Sulfur content	Gross weight	Sulfur content	Gross weight	Sulfur content

[1] In addition to countries listed Belgium, Brazil, China, Chosen, Eire, India, Japan, and U. S. S. R produced pyrites, but production data are not available.
[2] Data not available.
[3] Slovakia only.
[4] Estimated.
[5] January to October, inclusive.
[6] Average sulfur content of pyrites was 42 percent in 1931, latest year for which such information is available.
[7] January to July, inclusive.
[8] January to September, inclusive.
[9] Revised figures.

Australia.—Before the war Australian sulfur demand was supplied principally by imported elemental sulfur. As this trade dwindled under the pressure of shipping priorities, attention was given to the possibility of achieving self-sufficiency through pyrite. A pyrite industry already exists on Tasmania. Deposits at Eulaminna near Murrin, the Great Victoria at Burbridge, the Iron King at Norseman, and others at Spargo's Reward and St. Ives were explored.[17] During the latter part of 1942 it was reported that production of pyrite had begun.

Canada.—With Spanish pyrites available only intermittently during 1942, Canadian concentrates enjoyed a very good market in the United States. Aldermac was shipping at the rate of 16,000 tons monthly (12,000 tons from production and the rest from stock). The life of this mine was estimated early in 1942 at 16 months, as the ore body is near exhaustion.[18] Other pyrite-producing mines active in

1942 were the Noranda in Quebec and the Britannia in British Columbia. Prices on most contracts were 5 cents or better per unit.[19] Development of a property in Delestre Township, Quebec, was proposed by Delandore Iron & Sulphur Mines. Open-pit methods would be used on a deposit reported in 1937 to total 13,500,000 tons, containing 12 percent pyrite, and 88 percent pyrrhotite, which would concentrate to 37.5 percent sulfur and 54.5 percent iron.[20] A proposal was reported to install equipment in the Golden Manitou Mill in Quebec to enable it to recover 130 tons of pyrite per day from its zinc-gold-silver-pyrite ore.

Cyprus.—Pyrite production in Cyprus has virtually ceased as the island is in a critical and exposed position in the war zone.[21]

Eire.—After years of idleness, the pyrite deposits in County Wicklow are supplying sulfuric acid for the production of fertilizer from phosphate deposits in County Clare. The goal is to supply a quarter of Eire's normal consumption of superphosphate.[22]

Portugal.—During the first 10 months of 1942, 112,624 metric tons of pyrites were produced in Portugal.[23]

Spain.—In spite of Spain's enigmatic position in the war, it maintained its pyrites trade with Great Britain and to some extent with the United States. During the first 9 months of 1942, 162,417 metric tons were reported shipped to the United Kingdom through the ports of Huelva and Seville. Only 16,561 tons were exported to the United States in 1942—a mere fraction of the 1938–40 average (300,000 tons a year). American shipments were limited to Spanish ships, and no cargoes moved after September. In general, the evidence seems to agree that 1942 was a poor year for Spanish pyrites, and efforts were made to consume greater quantities within Spain, partly to benefit the industry but more particularly to relieve an acute shortage of arsenic and copper. Conversion of pyrites to more salable products was encouraged, and several plants took steps to install additional equipment for that purpose. The Seville Sulphur Copper Co. was ready to suspend operations owing to low quality and to transportation difficulties.[24]

Sweden.—Domestic production of pyrites increased as imports declined; but all sulfur supplies were very low, and some industrial activity was curtailed by the shortage.[25]

U. S. S. R.—Some reports indicate that in 1938 Russia was one of the leading pyrites producers, with an output approaching 1 million tons, derived chiefly from cupriferous ore bodies in the Urals and from coal mines.[26] Details are lacking for 1942, but it is certain that vast quantities of sulfur were required in the development and operation of Russia's large, rapidly expanding industries.

GENERAL CONDITIONS

The record for marketed production of phosphate rock made in 1941 was not quite attained in 1942, as the quantity sold or used by producers was 4,644,240 long tons (see fig. 1), about 45,000 tons less

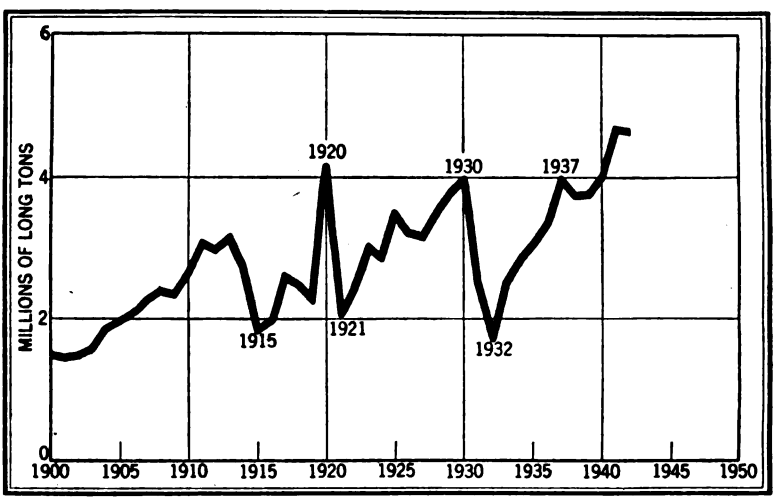

Figure 1.—Marketed production of domestic phosphate rock, 1900-1942.

than in 1941. The value, however, was about a million dollars greater than in 1941. Mined production—4,818,938 long tons in 1942—was 2 percent less than the all-time record of 4,922,183 tons in 1941. Exports fell nearly one-half million tons to 528,716 tons, whereas imports, a few thousand tons only, were slightly less than in 1941. Stocks in producers' hands at the end of the year increased 5 percent over 1941. Apparent domestic consumption of phosphate rock in 1942 was much the greatest ever recorded, exceeding 1941 by 12 percent.

Effects of war on world trade.—Before the onset of World War II international trade in phosphate rock was well established in certain definite channels; this commodity moved largely from three major producing centers—North Africa, the United States, and Oceania—to three principal consuming areas—Europe, Japan, and Australia and New Zealand. Two of the producing areas—North Africa and Oceania—exported virtually all of their production; that from North Africa went principally to Europe, but some was sent to Japan; and that from Oceania was split between Japan and the British Dominions Australia and New Zealand. The other important producing area, the United States, shipped only its surplus (about a third of its production). This went chiefly to Europe and Japan. Of the various consuming areas, Europe depended almost entirely upon imports, as did also Australia and New Zealand. Japan depended largely upon foreign sources, whereas the United States alone was entirely independent in respect to external supplies.

These normal world trade relations in phosphate rock have been almost completely upset by the war's developments. Each major development has reacted on international trade in this commodity. The outbreak of the war between the Allied Nations England and France and the German Reich on September 3, 1939, with the consequent British blockade of Germany, brought to a complete stop all exports of American and North African rock to Germany and the territory it controlled in central Europe—Austria, Czechoslovakia, Danzig, and Poland—except those that may have entered through the neutral Mediterranean countries in southeastern Europe.

With the invasion of Norway by Germany in April 1940, phosphate-rock shipments to the Scandinavian countries from the United States ceased, and in May 1940 the German invasions of Netherlands and Belgium ended all possibility of further shipments to those countries.

The defeat of France in June 1940 had many repercussions in the world phosphate-rock trade. It stopped the movement to Britain and the Union of South Africa from the North African deposits—normally the principal source of supply for this material—in consequence, Great Britain turned to the United States for supplies, and exports of American rock to Great Britain in 1940 exceeded even the large amount sent from the United States to Japan in that year. Large shipments were also made in 1940 from the United States to the Union of South Africa, which normally obtained its requirements from Morocco. Record shipments went to Canada from the United States, and American rock was sent to Portugal for the first time in many years. As a result of these new demands, exports from America were maintained at about 70 percent of the pre-war volume.

The entrance of Italy into the war as an Axis partner, following the collapse of France, stopped the shipments of American phosphate rock not only to Italy but also to countries such as Switzerland and Hungary that had been receiving American phosphates through Italian ports. The defeat of France and the entry of Italy into the war also had a very adverse effect on the phosphate industry of the French possessions in North Africa—Algeria, Morocco, and Tunisia—countries that normally produce about 4 million tons of rock a year and export about 3½ million tons to Europe. Shipments from French North Africa in 1940 and exports to Europe in that year are stated to have been only about 50 percent of those of 1939. Shipments were destined chiefly to France, Italy, and Spain. North African shipments moved to Germany through Italian ports. All exports from Tunisia in the latter half of the year and throughout most of 1941 went to Germany and Italy. Owing principally to the stoppage of Italian commerce through the Suez Canal by the British and to a great drop in shipments to Japan, phosphate exports from Egypt, which in 1938 and 1939 had amounted to over 400,000 metric tons a year, decreased to only 77,069 tons in 1940.

On September 20, 1940, Japan invaded Indochina, and 7 days later (September 27, 1940) joined the Berlin-Rome Axis, resulting in the cutting off of shipments of phosphate rock to Japan by Britain from Egypt, Nauru and Ocean Islands, and Christmas Island.

In 1941 two further major interferences in world trade in phosphate rock occurred. The first was the German attack on Soviet Russia in June 1941, which cut off imports of Russian apatite into Germany and initiated movement of the Kola Peninsula apatite from the port of

Digitized by Google

Murmansk to Britain and the United States. The second was the surprise attack on Pearl Harbor in the Hawaiian Islands on December 7, 1941, which brought the United States into the war on the side of Britain and stopped shipments from the United States to Japan.

Early in 1942 Japan conquered most of the phosphate-producing islands of Oceania (Nauru, Ocean, and Christmas Islands) and became self-sufficient in this commodity, fully compensating for the loss of imports from the United States, Egypt, and French possessions. This move by Japan also largely cut off the supplies to the British Dominions Australia and New Zealand, which had come principally from Nauru and Ocean Islands.

The world phosphate-trade picture changed again in November 1942 with United Nations occupation of the phosphate-bearing areas of French North Africa in Algeria, Morocco, and Tunisia, and German occupation of the former "unoccupied" portion of France. These events stopped the supplies of North African phosphates that had been going to France, Italy, and Germany and cut off the entire continental European market except the neutral coastal countries of Spain and Portugal, throwing the entire North African production on the remaining vastly restricted world markets in Allied and neutral countries in direct competition with American phosphate rock and also raising the possibility of invasion of the American domestic market by the French North African phosphate. The British Isles can now again get their supplies from French North Africa, releasing space on ships traveling from the United States to Britain and possibly eliminating much of the American export trade in this material. Australia and New Zealand—long cut off from their former sources of supply in Nauru and Ocean Islands—and the Union of South Africa can now obtain phosphate rock from North African sources.

Thus, at the beginning of 1943 Japan alone of the Axis Powers is self-sufficient in phosphate rock, whereas the European members have been cut off from the U. S. S. R. and all extra-European sources of supply and are limited to small, controlled European deposits, apparently inadequate for their economy. The United Nations, on the other hand, have at their disposal the great phosphate resources and industries of the United States and French North Africa—a supply far exceeding the needs of both Allied and neutral nations of the world.

PRODUCTION

Phosphate rock was mined in 1942 in Florida, Tennessee, Montana, Idaho, and Utah, and apatite was recovered from an apatite-ilmenite ore in central Virginia. Total mine production declined about 100,000 tons from the all-time record output reached in 1941.

Phosphate rock mined in the United States, 1933–42, by States, in long tons

SALES

For the third consecutive year in this decade the quantity of domestic phosphate rock sold or used by producers exceeded 4 million tons. In 1942 the phosphate rock sold or used was about 45,000 long tons less than the all-time record figure of 1941. Although its value was more than a million dollars greater than in 1941, it was still far below the record value of the boom year 1920.

Phosphate rock sold or used by producers in the United States, 1938–42

Year	Long tons	Value at mines		Year	Long tons	Value at mines	
		Total	Average			Total	Average
1938	3,739,238	$12,952,143	$3.46	1941 [1]	4,689,652	$15,596,273	$3.33
1939	3,757,067	12,294,042	3.27	1942	4,644,240	16,597,492	3.57
1940	4,002,700	12,334,662	3.08				

[1] Revised figures.

DISTRIBUTION OF SALES

Two distinct groups appear in the shipments of domestic phosphate rock by grades in recent years; one contains all phosphate rock of less than 60 percent B. P. L. (bone phosphate of lime) and the other all grades of 68 percent B. P. L. and higher. Both groups are increasing in size, and the gap between them is more distinct.

Seventy percent of the domestic phosphate rock sold or used by producers in 1942 is reported to have gone into the manufacture of superphosphates, and the quantity so consumed was over 400,000 tons greater than in 1941.

CONSUMPTION

The annual consumption of phosphate rock in the United States from 1867 to 1942 is shown in figure 2. The effect of World War II upon the domestic consumption of phosphate rock is well-shown by the abnormal extension of the line showing consumption above

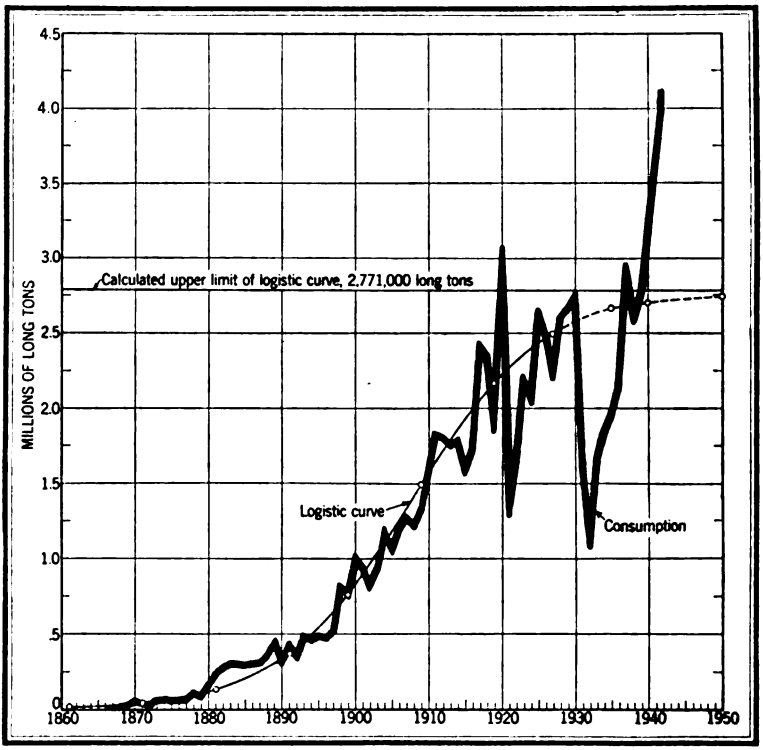

FIGURE 2.—Consumption of phosphate rock in the United States, 1867–1942.

the logistic curve indicative of the normal average demand. The apparent consumption in 1942 was 4,119,289 long tons, much the highest ever recorded.

PRICES

Trade-journal (Oil, Paint and Drug Reporter) quotations for the various grades of phosphate rock changed little during the first 10 months of the year. Maximum prices on Florida land-pebble phosphate rock and Tennessee brown-rock phosphate were established by the Office of Price Administration in a new schedule issued October 13, 1942, and effective October 19, 1942 (Maximum Price Regulation 240).

Near the close of the fiscal year ended June 30, 1942, the Office of Price Administration made plans for the Federal Trade Commission to study costs, prices, and profits in the fertilizer and related products industry. The inquiry began with a study of 11 important companies in the phosphate rock-mining industry.[6]

REVIEW BY STATES

Florida.—Another set-back to the growth of the Florida phosphate-rock industry occurred in 1942 (see fig. 3). The quantity of phosphate rock sold or used by producers in Florida—3,012,240 long tons—was 353,332 tons less than the 1941 sales; and, although the average value per ton increased from $3.04 to $3.11, the total value of the shipments was $855,454 less. The decrease was due to the greatly lessened foreign demand for Florida land pebble. The average values per ton for all types were higher in 1942. Sales of hard rock nearly doubled those of 1941, but the increase in sales of soft rock was slight.

Hard-rock-phosphate mining operations were conducted jointly by C. & J. Camp, Inc., and J. Buttgenbach & Co. in sec. 22, Citrus County, 3 miles from Hernando. The other hard-rock-phosphate company—the Dunnellon Phosphate Mining Co.—did no mining in 1942 but shipped hard rock from stocks. The Pembroke Chemical Corporation reported its sintering operations as permanently inactive, but this company together with the usual land-pebble producers mined and shipped land pebble.

Stocks of Florida phosphate rock reported by producers December 31, 1942, were 57,000 tons less than at the end of 1941 but still totaled 1,426,000 tons.

Mansfield [7] presents the results of a detailed study of the phosphate reserves of Florida. Total reserves are placed at 5,081,839,000 long tons, of which 2,058,583,000 are classified as known, 1,227,146,000 tons as probable, and 1,796,110,000 tons as possible. Reserves better than 74 percent B. P. L. total only 130,000,000 tons. Over two-thirds of the reserves are in the land-pebble and nearly one-third

Digitized by Google

in the hard-rock field. The phosphate rock resources of the Hawthorn formation and the Caloosahatchee marl are not included. Taylor [8] in the fourth article of a series describes some of the current practices in the field of land-pebble phosphate rock.

The International Minerals & Chemical Corporation completed in June 1942 its new Peace Valley mine, washer, and flotation plant, about a mile from Pembroke, on land leased from the Pembroke Chemical Co. Production began July 1, 1942. The output of this operation is sent to International's central drying and grinding plant at Mulberry, the drying capacity of which has recently been increased about 60 percent by the addition of a new 7- by 80-foot oil-fired rotary drier. Detailed descriptions of the Peace Valley Plant have been published.[9] The International Minerals & Chemical Corporation sold to Minerals Separation North American Corporation its half interest in the Phosphate Recovery Corporation, which the two companies had developed since 1928. It is also reported to have bought from the Phosphate Recovery Corporation the flotation plants serving its own phosphate mines.

Edwards [10] discusses in detail the electrical equipment of the completely electrified mines and plants of the International Minerals & Chemical Corporation in the Florida land-pebble-phosphate field and problems of maintenance of this equipment.

The process of separating phosphate by flotation on moving conveyor belts, in use in the land-pebble field at the Hopewell washer (6 miles from Coronet) by the Coronet Phosphate Co., is described in detail in a recent article.[11] Published descriptions also appeared of the froth-flotation and table-concentration plant of the Phosphate Mining Co. in the land-pebble field [12] and the new drying plant of the American Cyanamid Co.[13]

Tennessee.—The tonnage of phosphate rock sold or used by Tennessee producers in 1942 (plus a small quantity of apatite from Virginia) continued the upward trend of recent years (see fig. 3) and exceeded the all-time high of 1941 by 22 percent. The total value of the shipments likewise made a new high record, exceeding the previous record of 1920 ($4,857,399) by over a million and a quarter dollars. The greater part of the shipments were of brown rock, although a small quantity of blue rock drawn from stocks was used in research work by the Tennessee Valley Authority. Total stocks in hands of producers—brown rock and blue rock—at the close of 1942 were 437,000 long tons, an increase of 50 percent over the stocks on hand December 31, 1941.

[1] Separate figures for brown rock and blue rock cannot be given without disclosing confidential data regarding blue-rock production.

A few private companies and the Tennessee Valley Authority mined phosphate rock in Tennessee in 1942. The private companies include the Armour Fertilizer Works, Charleston Mining Co., Federal Chemical Co., Gilbreath & Pressnell, Harsh Phosphate Co., Hoover & Mason Phosphate Co., International Minerals & Chemical Corporation, Monsanto Chemical Co., and the Virginia-Carolina Chemical Corporation. The Charleston Mining Co., in operation during the first half of 1942, was dissolved and merged June 30, 1942, with its parent company, the Virginia-Carolina Chemical Corporation, which continued mining in Tennessee after the merger. Most of the brown-rock mining in this district is from surface operations.

The International Minerals & Chemical Corporation purchased additional phosphate-rock reserves in the Tennessee field in the fiscal year ended June 30, 1942, according to its annual report, and made further improvements in its mines and plants. Operating practices at this company's plants and at the remodeled phosphate-rock plant of the Virginia-Carolina Chemical Corporation were described in a recent article.[14]

The improvements at the plant of the Hoover & Mason Co. at Mount Pleasant have been described in recent articles.[15] A phosphate-rock grinding plant erected in 1942 on Swan Creek in Hickman County is said to have been operated only a short time.

In 1942 the Tennessee Valley Authority continued [16] its production of elemental phosphorus and phosphatic fertilizers. A plant formerly used for the production of phosphorus-carrying plant foods was enlarged and equipped to produce elemental phosphorus for the Chemical Warfare Service, and large quantities of that element were shipped for munitions manufacture. In June 1942 the Authority had one-fourth of the Nation's capacity for the production of munitions-grade phosphorus. Fertilizer production was continued to the extent that facilities were not needed for elemental phosphorus. The Authority sent about four-fifths of its production of triple superphosphate and calcium metaphosphate fertilizers to United Nations under lend-lease arrangement. The one-fifth reserved for domestic consumption was used in continuing cooperation with State agricultural extension services in a program of tests and demonstrations.

Construction of the Tennessee Valley Authority field phosphate plant in Maury County, Tenn., was completed, and the plant was put into operation during the summer of 1942. At the end of the year, approximately 500 tons of phosphate rock were mined a day, and the production of sinter amounted to about 190 tons daily. Phosphate mining, washing, and concentrating operations are carried out on the Authority's phosphate tract, about 5 miles from Columbia, Tenn., near Duck River. The plant at the phosphate tract consists of pit-mining equipment, a washer, water-pumping equipment, a hydroseparator, and auxiliary equipment. The phosphate sands from this plant are pumped approximately 3 miles to the classifying and finishing plant adjacent to the railroad at Godwin, Tenn. The Godwin plant consists of a rake classifier, bowl classifier, hydroseparator, Bird classifier, Dwight-Lloyd sintering machine, drier, and auxiliary equipment.

The Authority prospected nine farms covering 1,827 acres in 1942 and acquired options to purchase mineral rights on seven properties containing 1,117 acres. An option to purchase, in fee simple, a 141-acre tract in Williamson County was exercised.

Virginia.—Mining was continued at the Piney River nelsonite deposit in 1942 by the Southern Mineral Products Corporation, subsidiary of the Vanadium Corporation of America. The apatite-ilmenite ore (nelsonite) from the open pit was treated in its nearby mill, with separation of the apatite and ilmenite.

Western States.—Production of phosphate rock in the Western States has been increasing steadily in recent years. The quantity sold or used annually has about doubled in the last 5 years, reaching a record total of 265,665 long tons in 1942 (see fig. 3), with a value exceeding a million dollars for the first time. The production in 1942 came from Idaho, Montana, and Utah, as in 1941.

Idaho rock sold or used reached a new high in 1942 (114,079 long tons). Two companies were active in this State in 1942. Much the larger was the long-established producer—the Anaconda Copper Mining Co.—which operated its No. 3 mine at Conda, Caribou County. These operations have been described in considerable detail.[17] The other company in Idaho, the Teton Phosphate Co., Boise, shipped phosphate rock from Montpelier in February 1942 from its holdings near that place.

Montana was the largest producer of the Western States group in both 1941 and 1942 (see fig. 4). Its sales have increased sharply in recent years—from 44,384 long tons in 1939 to a new high record of 150,402 tons in 1942. In 1942 Montana had three producers. The largest—the Montana Phosphate Products Co. of Trail, British Columbia—operated the Anderson mine and several Federal leases in Powell County; it exported most of the mined phosphate rock to the Consolidated Mining & Smelting Co. of Canada at Trail. The other producers were the Mineral Hill Mining Co., Butte, Mont., which mined and shipped from its mine near Avon, Powell County, and L. H. Skeels, who shipped a small quantity from Maxville. The Northwestern Improvement Co., St. Paul, Minn., former lessee from the United States (Great Falls Serial No. 077838), conducted no mining operations thereunder in 1942 and on July 1 of that year assigned

[17] Mining World, Conda Operations of the ACM Company: Vol. 4, No. 10, October 1942, pp. 3-8.

Digitized by Google

the lease to the International Minerals & Chemical Corporation (formerly the International Agricultural Corporation). No production or shipments in 1942 were made by this company from the newly acquired property.

In Utah the Garfield Chemical & Mfg. Corporation mined and shipped phosphate rock from Federal-leased land near Spanish Fork, Utah County, in 1942, for use in pig-iron blast furnaces. During the year revised estimates of the phosphate reserves of Utah were published.[18]

On August 27, 1942, all deposits of vanadium and all public lands containing such deposits owned by the United States in Bannock,

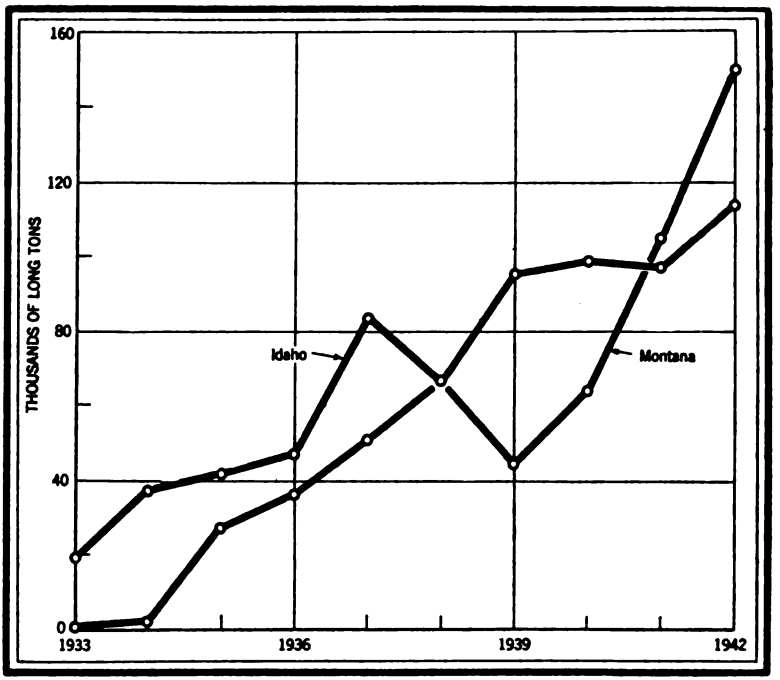

FIGURE 4.—Idaho and Montana phosphate rock sold or used by producers, 1933–42.

Bear Lake, Bingham, Bonneville, and Caribou Counties, Idaho; Rich County, Utah; and Lincoln, Sublette, and Teton Counties, Wyo., were withdrawn (Public Land Order 35, Abe Fortas, Acting Secretary of the Interior) from all forms of appropriation under the public-land laws of the United States, including the mining laws, and from leasing under the provisions of the mineral leasing laws relating to phosphate deposits and were reserved under the jurisdiction of the Secretary of the Interior for use in connection with prosecution of the war. The total area withdrawn, including both public and nonpublic lands, aggregated approximately 332,300 acres.

FOREIGN TRADE [19]

Imports.—Combined imports of apatite and phosphate rock in 1942 totaled 3,765 long tons compared with 4,340 tons (phosphate rock) in 1941. Although no apatite was imported in 1941, in April 1942 a considerable quantity, 920 long tons, was received from the U. S. S. R. Apparently part of this has been included under "Phosphates, crude, not elsewhere specified" in the accompanying table. In May 1942 2,800 long tons of Curaçao phosphate rock were imported.

Phosphate rock and phosphatic fertilizers imported for consumption in the United States, 1938–42

Slag, basic, ground or unground	691	9,547	405	5,168	452	4,766	------	------	894	1,011
Precipitated bone, fertilizer grade	3,385	98,725	2,314	68,611	1,141	38,225	------	------	23	851

Exports.—The export trade of the United States in phosphate rock has reacted to the vicissitudes of the present World War. Not only is it much smaller than normal, but the domestic rock is no longer shipped to widely scattered parts of the world. Exports are restricted almost entirely to Canada and the United Kingdom.

[19] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

[1] 1938–40: Excludes sintered matrix, which is included under "Other phosphate materials." 1941–42: Excludes "Phosphate rock: Florida: Other (including soft rock, colloidal and sintered matrix)," which is included under "Other phosphate materials."

[2] For statistical purposes, trade with the Sudeten area, as far as ascertainable, is included with Germany while trade with the other Czechoslovak Provinces occupied by Germany, Hungary, and Poland has been included with these countries, since March 18 or 19, 1939. After November 16, 1939, trade with Danzig and that part of Poland occupied by Germany has been included with Germany, and trade with that part of Poland occupied by U. S. S. R. has been included with U. S. S. R.

[3] United Kingdom of Great Britain and Northern Ireland.

TECHNOLOGIC DEVELOPMENTS

Several papers [20] on various phases of phosphate-rock technology, in addition to those mentioned in other parts of this chapter, have appeared in recent months.

SUPERPHOSPHATES

The following table gives the outstanding features of the superphosphate industry in the United States from 1940 to 1942:

Salient statistics of the superphosphate industry in the United States, 1940–42

	1940	1941	1942
Production [1] ..... short tons	3,898,641	4,326,402	5,144,484
Shipments,[1] total ..... do	2,934,336	3,633,871	3,961,362
To mixers ..... do	1,530,474	1,638,026	1,916,772
To other acidulators (including exchange transfers) ..... do	471,855	659,514	541,225
To all others (including Government agencies) ..... do	932,007	1,336,331	1,503,365
Stocks in manufacturers' hands, Dec. 31 [1] ..... do	1,142,585	932,683	973,224
Exports of superphosphates [2] ..... long tons	141,289	146,875	165,092
Imports of superphosphates [2] ..... do	10,017	17,368	16,659
Sales of phosphate rock by producers for superphosphate production ..... long tons	2,564,844	2,825,456	3,242,689

Superphosphates (acid phosphates) imported for consumption in the United States, 1940–42, by classes [1]

Class	1940		1941		1942	
	Long tons	Value	Long tons	Value	Long tons	Value
Normal (standard) (not over 25 percent P_2O_5 content)	7,057	$97,682	12,017	$172,990	5,965	$80,409
Concentrated (treble) (over 25 percent P_2O_5 content)	2,864	39,982	5,333	133,835	10,694	300,342
Ammoniated	96	1,951	18	376		
	10,017	139,615	17,368	307,201	16,659	380,751

[1] All from Canada.

Several articles relating to the superphosphate industry have appeared in recent months.[21]

BASIC SLAG

No recent figures for the production of basic slag are available. In Great Britain, however, the production is said to have increased substantially during the present war, and this is probably likewise true of some of the Axis-controlled nations. In the United States only a few thousand tons of basic slag are produced annually—in the Birmingham iron district, Alabama—and a few hundred tons is imported a year. Phosphatic slag is produced at the steel furnaces at Sydney, Nova Scotia, and the Canadian Government is investigating its possible agricultural utilization.

TALC, PYROPHYLLITE, AND GROUND SOAPSTONE [1]

By Bertrand L. Johnson and K. G. Warner

SUMMARY OUTLINE

	Page		Page
General conditions	1381	Prices	1385
Salient statistics	1382	Developments in the industry	1385
Sales	1383	Foreign trade	1387
Markets	1384	World production	1389

GENERAL CONDITIONS

Declines in the demand in several industries for talc, pyrophyllite, and ground soapstone depressed both the mined production and the quantity sold and used in 1942 to levels below those of 1941. Sales in 1942 were 387,963 short tons, a 7-percent decrease from 1941;

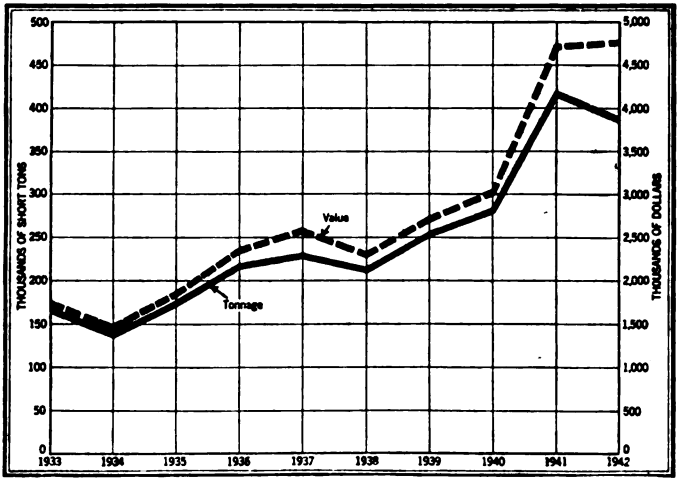

FIGURE 1.—Sales of domestic talc, pyrophyllite, and ground soapstone, 1933–42.

however, the total value of sales—$4,754,076—was the highest on record. (See fig. 1.) Sales of crude, sawed and manufactured, and ground all decreased in quantity, but only the crude is reported to have decreased in value. All classes of imports were less in quantity and, with the exception of the crude, lower in value. Exports declined both in quantity and value.

Pyrophyllite is included with talc in this discussion because it resembles talc in certain physical properties and is interchangeable

[1] Soapstone sold in slabs or blocks is included in the chapter on Stone.

Digitized by Google

with talc in some uses, although during recent years certain specialized uses for pyrophyllite have been developed. It is a hydrous aluminum silicate, $Al_2Si_4O_{10}(OH)_2$, whereas talc is a hydrous magnesium silicate. Pyrophyllite sometimes is classed as one of the kaolin minerals. Production and sales figures for pyrophyllite are available for publication separately in 1942 for the first time.

Salient statistics of the talc, pyrophyllite,[1] and ground-soapstone industries in the United States, 1941–42

	1941		1942	
	Short tons	Value	Short tons	Value
Mined:				
Total	414,544	(2)	403,801	(2)
Used by producers	370,444	(2)	354,126	(2)
Sold by producers—				
Crude [3]	43,823	$393,839	33,837	$303,166
Sawed and manufactured	4,186	308,467	1,505	370,631
Ground	368,360	3,999,586	352,621	4,080,279
	416,369	4,701,892	387,963	4,754,076
Imports for consumption: [4]				
Crude and unground steatite and French chalk	341	5,780	292	5,849
Cut and sawed	71	10,611	(5)	36
Ground, washed, or pulverized	18,225	225,857	8,487	94,591

		1,445,720		870,213

[1] Bureau of Mines not at liberty to publish pyrophyllite figures separately for earlier years. In 1942: Mined, 53,247 short tons. Sold—crude, 6,440 tons, $35,790; ground, 47,229 tons, $379,026; total, 53,669 tons, $414,816.
[2] Data not available.
[3] Includes pinite from Nevada.
[4] Exclusive of "manufactures, n. s. p. f., except toilet preparations," as follows: 1941, $11,701; 1942, $2,704. Quantities not available.
[5] Less than 1 ton.
[6] Quantity not recorded.

Thirteen States reported sales of talc, pyrophyllite, ground soapstone, or pinite in 1942—2 more than in 1941. Alabama and New Mexico were new producers. The Eastern States furnished 83 percent of total domestic sales, the same as in 1941.

Descriptions have recently been published of several domestic talc deposits.[2]

To provide adequate supplies of steatite talc for military use and to prevent its dissipation into uses for which suitable substitutes were available, the War Production Board issued Conservation Order M–239 October 13, 1942, forbidding the use, sale, and delivery of steatite talc except for (1) insulators in communications, radio, radar, and underwater sound instruments; (2) spark plugs for certain war industries; (3) filtering of foods, flavoring extracts, and medicines; and (4) medicines and health supplies, but not including talcum powder or cosmetics. This order was amended February 6, 1943, and certain essential uses formerly forbidden were permitted. These included its

use in electrical and heat insulating products (not including refractories), electric light bulbs, and experimental work. Changing conditions in the talc industry, altering the supply and demand situation, resulted in the issuance on April 29, 1943, by the War Production Board of another amendment to M–239, which removed the existing restrictions on the delivery and use of steatite talc for other than specified uses, established control over production and grading of steatite talc, provided a system of inventory control based upon maximum consumer stocks, and released all frozen stocks of steatite talc purchased before the original issuance of M–239 on October 13, 1942.

Stock-piling of steatite talc was started by Metals Reserve Co. early in 1943.

SALES

In 1942 producers sold or used 28,406 short tons less of talc, pyrophyllite, and ground soapstone than in 1941, but because of an increase in average value the total value of the sales was $52,184 greater, reaching a new all-time high record of $4,754,076. Sales of crude, sawed and manufactured, and ground materials were all lower in 1942 than in the previous year.

Talc, pyrophyllite,[1] *and ground soapstone sold by producers in the United States, 1938–42, by classes*

Year	Crude			Sawed and manufactured

[1] Bureau of Mines not at liberty to publish pyrophyllite figures separately for earlier years. In 1942: Crude, 6,440 tons, $35,790; ground, 47,229 tons, $379,026; total, 53,669 tons, $414,816.
[2] Includes pinite from Nevada.

Sales by States.—The tonnages sold or used by producers declined in most of the States for which comparative figures can be shown for 1941 and 1942. Declines were greatest in New York (11 percent), North Carolina (12 percent), and California (13 percent). Georgia was the only State in 1942 to attain a new all-time high record. New York was by far the outstanding producer, and its output was double that of any other State. North Carolina was the only State marketing pyrophyllite. Sales figures for this commodity are available for publication for the first time.

Other States [3]	24,252	142,196	26,388	178,332
	416,369	4,701,892	[2] 387,963	[2] 4,754,076

[1] Includes pinite.
[2] Includes pyrophyllite from North Carolina as follows: 53,669 tons, valued at $414,816; Bureau of Mines not at liberty to publish figures separately for earlier years.
[3] 1941: Montana, Pennsylvania, and Virginia; 1942: Alabama, Montana, New Mexico, Pennsylvania, and Virginia.

MARKETS

Five industries—paint, roofing, ceramics, rubber, and paper—consumed 76 percent of the domestic sales of talc, pyrophyllite, and ground soapstone in 1942, according to reports from producers to the Bureau of Mines. Of these five, the paint and roofing industries alone showed increases. The paint industry consumed over 5,000 tons more than in 1941, taking 32 percent of the total compared with 29 percent in 1941. Roofing was the second-largest consuming industry, rising from fourth to second place and consuming 20 percent more in 1942 than in 1941. The ceramic industry, in second place in 1941, took 39 percent less in 1942 than the previous year or a little less than the roofing industry, thus falling into third place. The rubber industry also declined sharply as a market for these commodities (30 percent), going from third to fourth place. Use in paper declined 20 percent but remained in fifth place.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1941–42, by uses

Use	1941		1942	
	Short tons	Percent of total	Short tons	Percent of total
Paint	120,319	29	125,518	32
Ceramics	78,990	19	48,372	13
Rubber	58,114	14	40,487	10
Roofing	40,605	10	48,870	13
Paper	37,884	9	30,440	8
Toilet preparations	21,119	5	18,902	5
Insecticides	10,479	2	15,810	4
Foundry facings	6,705	2	7,822	2
Crayons	3,186	1	1,474	(1)
Other uses reported [2]	24,280	6	27,631	7
Use not reported	14,688	3	22,637	6
	[3] 416,369	100	[3] 387,963	100

[1] Less than 0.5 percent.
[2] 1941: Bleaching, insulation, lubricants, refractory, textile, and other minor uses; 1942: Refractory, chemical war service, insulation, plastics, bleaching, textile, lubricants, and other minor uses.
[3] Includes pinite.

PRICES

The average values of sales of all grades of talc, pyrophyllite, and ground soapstone in the past 5 years, as reported to the Bureau of Mines by producers, are given in the table under Sales.

Quotations on ground domestic talc, per ton, f. o. b. works, on June 21, 1943, according to the Oil, Paint and Drug Reporter, were as follows:

California: $17.50 to $43.00.

New York: Fibrous, coarse, off-color, $13.00. Fine, 325-mesh, 93 to 94 percent, $13.00 to $18.00; 98 to 99.5 percent, $15.25 to $19.25; 99.85 to 99.95 percent, $17.00 to $21.00.

Pennsylvania: $11 to $13.50.

Vermont: $14.00.

Canadian talc, bags, carlots, per ton, $24.00 to $30.00.

The quoted prices on pyrophyllite in the same journal were: Standard, 200-mesh, carlots, paper bags, mines, per ton, $10.00; 325-mesh, same basis, ton, $13.00; No. 3, 200-mesh, carlots, mines, ton, $8.00; 325-mesh, same basis, $11.00.

DEVELOPMENTS IN THE INDUSTRY

Talc.—Thurnauer and Rodriguez [3] define "steatite" as a group of ceramic materials that contain hydrous magnesium silicate (talc or soapstone) as a predominant constituent in the unfired condition. A survey of the literature on the crystal structure of calcined talc and steatite materials is given. The changes in the structure of four typical talc and steatite bodies brought about by varying heat treatment and by the addition of different fluxes were studied. Only two crystal modifications of magnesium metasilicate were observed under the conditions of the investigation. One was the unstable form, protoenstatite, and the other the stable modification, clinoenstatite. Great differences in the rate of crystal growth and extent of polymorphic transformation of one magnesium metasilicate modification into another were observed in the different bodies. Protoenstatite was always found during the early stages of firing or when the crystals remained small, whereas clinoenstatite appeared when the crystals were large. Weakening of the body appeared to be caused by the mechanical cracking of the large crystals of clinoenstatite. Provided the crystals are kept small enough (—7 microns) the body would remain dense, regardless of the number of firings it received.

Relatively small quantities of steatitic talc porcelains were used before the war in radio equipment; their main ingredient was hand-picked talc, largely from a single California source.[4] With the development of a greatly increased war demand, the location of additional sources became imperative. Most talcs are unfit for use in these highly specialized bodies, as they usually contain too much iron and lime as impurities. Some talcs, however, may be beneficiated and brought up to grade—that is, having a content of less than 1 percent each of Fe_2O_3 and CaO. A talc giving excessive firing shrinkage is also undesirable, and the final test of suitability is whether a fired ceramic

Digitized by Google

body containing the talc makes an acceptable insulator. The Bureau of Mines made a Nation-wide search for talcs meeting these specifications. Field engineers inspected the deposits and collected the samples, which were analyzed and evaluated at the Tuscaloosa (Ala.) laboratory. Beneficiating tests were made on all but the most hopeless, and if the results were at all promising large batches were beneficiated and prepared for testing at the Norris (Tenn.) laboratory in regular bodies for electrical and other properties. Some promising talcs were found in California and Alabama. In the East there are large talc deposits in Alabama, North Carolina, Virginia, and New York, which seem unusually good, especially if processed according to modern flotation milling methods. The Bureau of Mines developed methods for treating domestic talcs and processed several million radio insulators.

Late in 1942 Gunzenhauser[5] presented the third of a series of articles on steatite and special ceramic materials used for electrical insulating parts; he discussed the physical properties of such materials in this latest paper.

The use of a steatite body by the Star Porcelain Co., Trenton, N. J., in the manufacture of porcelain welding ferrules is described in a recent article.[6]

Hendricks[7] discussed the lattice structure of talc and pyrophyllite.

Rigterink, Grisdale, and Morgan[8] prepared a number of steatite bodies under carefully controlled conditions and measured their dielectric losses and direct-current resistances at elevated temperatures. It was found that variations of the ratio of talc to kaolin within certain limits had little effect on the dielectric properties. These properties, however, were changed to a considerable extent by varying the amounts, proportions, and kinds of alkaline-earth oxides added as fluxes. The data indicate also that the conditions in a ceramic body favorable to a high specific resistance are not necessarily those favorable to a low dielectric loss.

The results of tests on the thermal-expansion characteristics of steatite by Rigby and Green, originally published in 1941, were reprinted in 1942.[9]

Tremolitic talc dust has been classed as a silicate dust capable of causing a disabling pneumoconiosis.[10] Other papers relating to talc as an occupational hazard are those by Schultz and Williams[11] and Snyder.[12]

Pyrophyllite.—The pyrophyllite open-pit mine and mill of the Carolina Pyrophyllite Co., Randolph County, N. C., are described

in a recent article.[13] Air drills are used in mining. The broken pyrophyllite, hand-loaded on 6-ton trucks, is dumped into open storage or bins at the mill. It is crushed in a 12- by 24-inch Reliance jaw crusher set to 1 inch; the crushed material is then elevated to two surge bins, one for each of the two mill units. Each of these units is equipped with a Hardinge conical mill, 8 feet by 36 inches in one and 8 feet by 80 inches in the other, each being followed by a 14-foot Gayco separator. Oversize from each separator is sent back to the corresponding mill. The finished material is delivered to a bin, from which it is shipped in bulk or bagged. Salisbury (N. C.) granite blocks are used to line the Hardinge mills; this granite is also used as the grinding medium, replacing Belgian flint pebbles. Ground products shipped range from 80- to 325-mesh. Rock crushed to one-half inch and three-fourths inch has also been shipped.

Hendricks' discussion of the lattice structure of pyrophyllite has already been mentioned.[14]

FOREIGN TRADE[15]

Imports.—Total talc, steatite or soapstone, and French chalk imports in 1942 dropped 53 percent in quantity and 59 percent in value

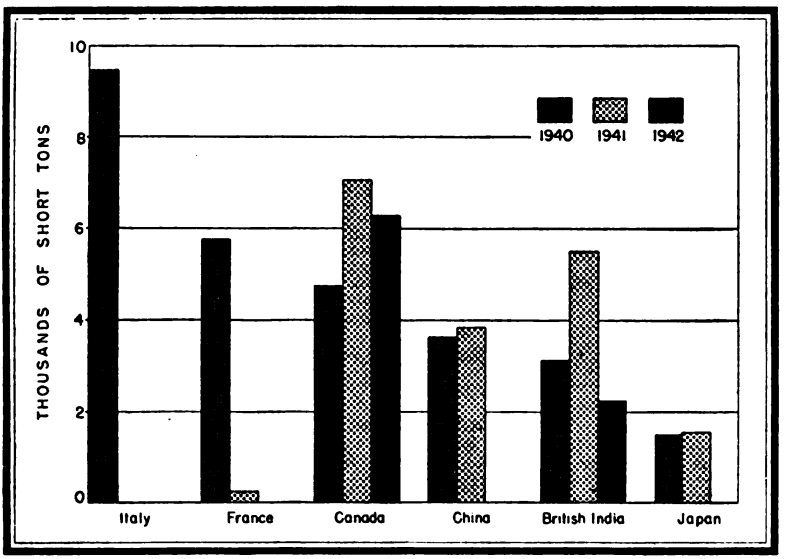

FIGURE 2.—Talc, steatite or soapstone, and French chalk imported for consumption in the United States, 1940–42, by leading countries.

from 1941. Nearly all of the imports consisted of materials "ground, washed, powdered, or pulverized, except toilet preparations," only a few hundred tons being of "crude and unground" and "cut and sawed" materials. India furnished 286 tons of crude block steatite, as well as considerable ground steatite. Imports in 1942 came principally from Canada and British India (see fig. 2); only minor

quantities came from Japan and United Kingdom. Imports incorrectly reported as from Kwantung (Japanese-leased territory) in the import tables in the Talc chapter, Minerals Yearbook 1941 (p. 1397), actually came from British India.

Steatite talc imports were placed under import control November 23, 1942 (General Imports Order M–63, December 27, 1941, Federal Register, vol. 6, No. 252, December 30, 1941, pp. 6796–6797, as amended November 20, 1942, Federal Register, vol. 7, No. 230, November 24, 1942, pp. 9702–9703).

Exports.—The quantity of "talc, steatite, soapstone, and pyrophyllite, crude and ground" exported from the United States reached an all-time record of 10,889 short tons in 1941 but was 1,643 tons less in 1942. The value of "powders—talcum (in packages), face, and compact," exported in 1941 was higher than in any year since 1931, but the value of the exports in 1942 was 45 percent less than in 1941.

Talcum and other powders exported from the United States, 1938–42

Year	Description	Short tons	Value	
			Total	Average
1938	Talc, steatite, and soapstone, crude and ground	7,118	$124,194	$17.45
	Powders—talcum (in packages), face, and compact	(1)	978,100	
1939	Talc, steatite, and soapstone, crude and ground	9,047	162,426	17.95
	Powders—talcum (in packages), face, and compact	(1)	1,115,176	
1940	Talc, steatite, and soapstone, crude and ground	9,402	167,992	17.87
	Powders—talcum (in packages), face, and compact	(1)	945,530

[1] In addition to countries listed talc or pyrophyllite is reported produced in Brazil, Bulgaria, U. S. S. R., and Western Australia but data on production are not available.
[2] Data not available.
[3] Excludes soapstone, which is reported only by value and was as follows: 1937, $40,513; 1938, $35,038; 1939, $41,471; 1940, $74,905; 1941, $155,925; 1942, $121,766. Soapstone is sold in the form of both blocks and powder.
[4] January to September, inclusive.
[5] Includes steatite, as follows—1937: 500 tons; 1938: 3,480 tons; 1940: 17,191 tons.
[6] Talc, pyrophyllite, and ground soapstone sold by producers; includes also pinite in 1940, 1941, and 1942.
[7] January to June, inclusive.

Digitized by Google

Canadian talc and soapstone developments in 1941 have been described as follows:[16]

Active production of ground talc in Canada was begun in 1906 from deposits in the Madoc area, Ontario, and these deposits have since been the main source of supply. Canada Talc, Limited, is the chief producer in the area, having taken over the holdings of G. H. Gillespie Company, the pioneer operator, in 1937. There have been various other small operations in the area. In 1941, Trent Mining Syndicate began to develop a property adjoining that of Canada Talc, Limited, where surface showings indicate an easterly extension of the same vein system, and at the end of the year was proceeding with the erection of a small mill. R. W. Bonter and associates of Trenton ground a small tonnage of slightly off-color talc in the mill of Canadian Slate Products, a mile and a half north of Madoc; the crude was brought in by truck from a deposit operated by W. C. Spry near Ompah, Frontenac County, 65 miles distant. The talc from Ompah is finely schistose, cream-colored, and distinct in character from the white foliated talc of the Madoc district.

In British Columbia, the deposits near McGillivray, on the Pacific Great Eastern Railway, and at Kapoor, near Victoria, have been idle since 1935. The crude was shipped to a grinding plant at Vancouver, for local roofing use.

Quebec has been supplying soapstone in small quantities since 1922, and the industry has been supplying mainly blocks and bricks for alkali recovery furnaces of domestic kraft mills. Some cut furnace stone has been exported. In recent years the sawing of crayons has been undertaken. Broughton Soapstone and Quarry Company, the principal operator, has developed a large quarry near Leeds Station on the Quebec Central Railway, in Broughton Township. This company produces cut furnace stone and crayons and has a grinding mill in which quarry and sawing waste, as well as a more highly talcose rock occurring in a band cutting its main soapstone body, are pulverized. The company took over the Louis Cyr holdings at St. Pierre de Broughton in 1940. Other operators in the same area are Charles Fortin, of Robertson, and L. C. Pharo, of Thetford Mines. L. C. Pharo installed a small grinding unit on his property in Thetford township in 1938. Some of the dust from these operations is sold to domestic roofing firms, and a considerable tonnage of quarry and sawing waste is shipped to the grinding plant of Pulverized Products, Limited, 4820 Fourth Avenue, Rosemount, Montreal. Baker Mining and Milling Company, 4010 St. Catherine Street West, Montreal, the only other operator in Quebec, has a mine and mill near Highwater in Potton township, Brome County, close to the Vermont line.

Extensive studies on steatite deposits in Canada are reported, and a steatite industry is said to have been established.[17] In Quebec the output of talc and soapstone in 1942 increased over 1941.[18]

In the U. S. S. R. the large agalmatolite deposits in the Ak-Tash region of Central Asia and tests of this material for porcelain and faience production were described recently by Vikhireva.[19]

Steatite was produced in Western Australia in 1942.[20]

FLUORSPAR

SUMMARY

The period of intense activity in fluorspar mining, which began in 1940, continued unabated throughout 1942. Despite some strikes, manpower shortage, and other handicaps, production and shipments (337,000 and 360,316 short tons, respectively) in 1942 were 8 and 12 percent greater than in 1941, the previous record year, and shipments were 37 percent more than in 1918 during World War I. Attaining first place in 1942, Illinois shipments (161,949 tons) exceeded by 3.4 percent the previous high (156,676 tons) reached in 1917. New Mexico and Utah also established new records in 1942. Shipments from Kentucky in 1942 were 6 percent under the all-time record made in 1941. Shipments by river or river-rail (79,049 tons) also made a new record in 1942. However, imports, amounting to 2,151 tons, declined 71 percent from 1941 and were smaller than in any year since records were first kept (1910). Exports, which are usually small, decreased 26 percent but for the second time exceeded imports.

During 1942 much prospecting and development work were done; probably more shafts were sunk and more mills were constructed than in any one previous year. However, because of a shortage of labor and the need to use most of the available manpower to mine ore, many producers could not keep their development as far ahead of mining as was desirable.

Notwithstanding the record production of fluorspar in 1942, the output of metallurgical grade did not keep pace with consumption; as a consequence, inventories at consuming plants declined substantially. Fortunately, the monthly survey of fluorspar, inaugurated by the Bureau of Mines in January 1942, reflected the lag in production in the early part of 1942, and the War Production Board was able to take corrective action much sooner than would have been possible had monthly data not been available. Among other things this action included an extensive examination of deposits in the Illinois-Kentucky district and in the West by the Geological Survey, a drilling and development program in these areas by the Bureau

[1] Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce; those on exports of fluorspar supplied by the producers.

Digitized by Google

of Mines, an increase in maximum price, and a change in specifications. Based upon the field work of the Bureau of Mines and upon data made available from other sources, a number of war minerals reports [2] on fluorspar have been prepared for the confidential use of Federal war agencies.

Salient statistics of the fluorspar industry in the United States, 1941–42

	1941		1942	
	Short tons	Value	Short tons	Value
Shipments from domestic mines—

[1] Figures not available. [3] Revised figures.

Despite the fact that demand for metallurgical-grade fluorspar was supplied with some difficulty, no prohibitions or limitations were placed on its use, but the War Production Board requested steel manufacturers to employ fluorspar as sparingly as possible. Although supplies of metallurgical-grade fluorspar were not allocated during 1942, it was necessary to divert shipments to certain consumers who had inadequate supplies. However, beginning January 1943 shipments of both metallurgical and ceramic grades will be controlled by the War Production Board, which will forbid any supplier to ship fluorspar to consumers having an inventory greater than a "practicable working minimum."

Although consumption of acid-grade fluorspar gained remarkably

in 1942, production increased still more and in consequence inventories were larger at the end than at the beginning of 1942. Likewise, production of ceramic-grade fluorspar was more than adequate for consumption which, however, declined in 1942.

Recognizing the importance of fluorspar in the military program, representatives of the Army Air Forces spent considerable time studying the fluorspar plants in southern Illinois; as a result, the Forces took over the responsibility of protecting the plants at Rosiclare against sabotage and other malicious damage. The properties have been fenced, and each plant has a regular force of guards.

At Rosiclare, Ill., a Government housing project involving an expenditure of approximately $500,000 was started to provide housing facilities for 150 families.

Sales of fluorspar to consumers in the United States totaled 353,469 short tons in 1942 (351,300 tons from domestic mines and 2,169 tons from foreign sources) compared with 316,074 tons in 1941 (308,485 tons from domestic mines and 7,589 tons from foreign sources). Total sales to steel plants in the United States advanced to 225,502 tons in 1942 from 220,222 tons in 1941, and sales to domestic manufacturers of hydrofluoric acid (essential in the manufacture of artificial cryolite and aluminum fluoride—aluminum raw materials) increased to 89,983 tons from 54,092 tons, but sales to domestic makers of glass and enamel declined to 22,813 tons from 32,051 tons.

The greatly accelerated demand for fluorspar in 1942 was accompanied by an advance in prices. The average composite selling price ($24.66) of all grades (both domestic and foreign) delivered to consumers in the United States was $3.68 more than in 1941 ($20.98). The average selling price f. o. b. Illinois-Kentucky mines of fluorspar shipped to domestic steel plants was $23.82 a short ton ($19.62 in 1941), of that shipped to domestic manufacturers of hydrofluoric acid $28.86 ($26.78 in 1941), and of that shipped to domestic makers of glass and enamel $29.44 ($27.39 in 1941).

Effective November 23, 1942, the Office of Price Administration established new base ceiling prices for metallurgical-grade fluorspar ranging from $25 to $28 a short ton according to calcium fluoride and silica content. These prices compared with previous prices of $23 to $25 a ton for standard metallurgical grade in the Illinois-Kentucky district. The new prices are subject to freight adjustments. At the same time, a price of $32 a short ton, subject to freight adjustments, was established for acid-grade fluorspar (except in the Illinois-Kentucky district) containing a minimum of 97½ percent calcium fluoride and a maximum of 1½ percent silica.

In the trade agreement between the United States and Mexico, the duty on fluorspar containing not more than 97 percent calcium fluoride was lowered to $5.62½ a short ton from $7.50.

The total quantity of fluorspar shipped in and imported into the United States from about 1870 through 1942 was approximately 6,270,000 short tons, comprising 5,209,000 tons from domestic mines and 1,061,000 tons from foreign sources.

PRODUCTION AND SHIPMENTS

Production of fluorspar (expressed in terms of finished product) totaled 337,000 short tons in 1942 compared with 313,000 tons in 1941. Of the output in 1942, 10 mines producing over 10,000 tons

Digitized by Google

each supplied 156,000 tons or 46 percent, 12 mines producing 5,000 to 10,000 tons each supplied 83,000 tons or 25 percent, and 26 mines producing 1,000 to 5,000 tons each supplied 65,000 tons or 19 percent; thus, 48 mines produced 304,000 tons or 90 percent of the total. The remainder (33,000 tons or 10 percent) was produced in quantities ranging from a few tons to 1,000 tons from an undetermined number of small mines and prospects and reclaimed from waste dumps and old workings of abandoned mines.

Fluorspar shipments from domestic mines in 1942 aggregated 360,316 short tons valued at $8,897,749, increases of 12 percent in quantity and 32 percent in total value over 1941, and were the largest on record. Of the 1942 total, 79,049 tons (an all-time high) was shipped by river or river-rail for delivery to consumers in Illinois, Indiana, Kentucky, Ohio, Pennsylvania, and West Virginia.

Illinois (45 percent) and Kentucky (37 percent) supplied 82 percent of the fluorspar shipped in 1942 compared with 86 percent in 1941. Shipments from the Illinois-Kentucky district in 1942 gained only 7 percent over 1941 compared with an increase of 44 percent in the West.

In 1942 mines operated by consumers shipped about 92,000 short tons of fluorspar for use in their own plants compared with 59,644 tons in 1941.

The average value of all grades of domestic fluorspar shipped in 1942 was $24.69 a short ton ($3.72 more than the 1941 average).

The following table shows shipments of fluorspar, by States, 1941 and 1942. (For historic table, see Minerals Yearbook, 1941, p. 1401.)

Fluorspar shipped from mines in the United States, 1941–42, by States

State	1941			1942		
	Short tons	Value		Short tons	Value	
		Total	Average		Total	Average
Colorado	15,566	$225,069	$14.46	31,743	$640,938	$20.19
Illinois	133,333	3,047,247	22.85	161,949	4,306,750	26.59

	320,669	6,724,782	20.97	360,316	8,897,749	24.69

Ferrous and nonferrous plants are the chief purchasers of fluorspar, taking 66 percent of the total shipped from domestic mines in 1942. Of the fluorspar shipped to these plants in 1942, 97.9 percent was metallurgical grade, 0.5 percent ceramic grade, and 1.6 percent acid grade. Chemical plants, which use acid-grade fluorspar, and glass and enamel makers, which use fluorspar varying widely in calcium fluoride and silica content, took 25 and 6 percent, respectively, of the domestic shipments in 1942.

The next table shows shipments of fluorspar, by grades and industries, in 1942.

Exported	9,016	242,545	26.90
	360,316	8,897,749	24.69

[1] Of this quantity 2,985 tons were unground, including 2,602 tons of a purity equivalent to metallurgical grade.

SHIPMENTS, BY USES

The steel industry is the predominant purchaser of fluorspar, as is evident from the following table; it also consumes considerable hydrofluoric acid and sodium fluoride, in which fluorspar is the basic material.

Fluorspar shipped from mines in the United States, 1941–42, by uses

Use	1941				1942			
	Quantity		Value		Quantity		Value	
	Percent of total	Short tons	Total	Average	Percent of total	Short tons	Total	Average
Steel	66.77	214,120	$4,048,454	$18.91	62.51	225,233	$5,085,037	$22.58

USES

As figure 1 shows graphically, the steel industry is the chief consumer of fluorspar in the United States. Fluorspar is used as a flux in basic open-hearth and basic electric steel furnaces; a comparatively small amount is used in Bessemer-steel furnaces. The second-largest

Digitized by Google

use is in the manufacture of hydrofluoric acid, which is employed to make artificial cryolite and aluminum fluoride (aluminum raw materials) and refrigerating mediums; hydrofluoric acid is also used in the electrolytic refining of metals, the pickling of metals, chromium plating, the processing of high-octane gasoline and synthetic rubber, and the etching of glassware, as well as for other purposes. The glass industry, which uses fluorspar as an opacifier and as a flux, ranks third in importance. The enamel industry uses fluorspar as an ingre-

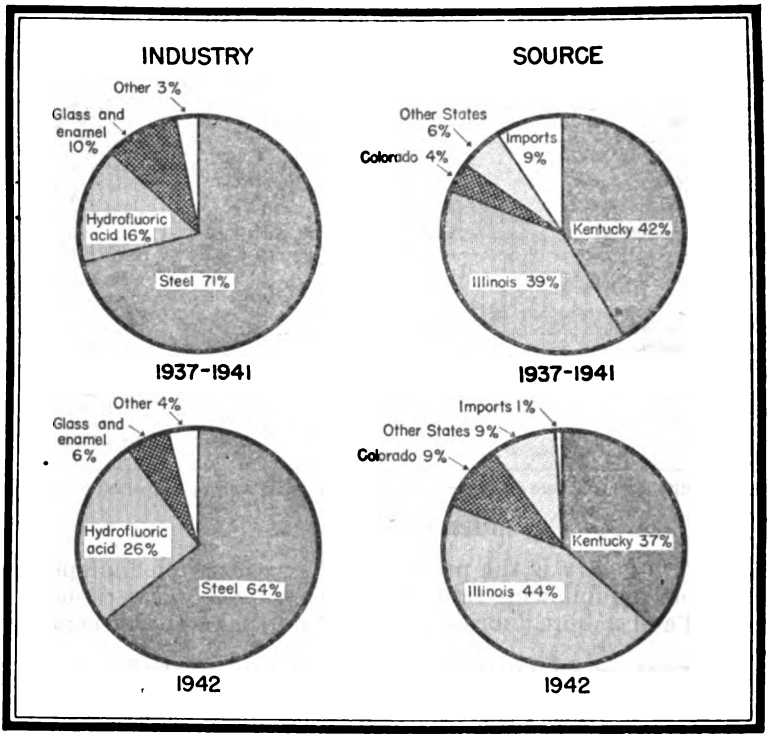

FIGURE 1.—Average annual fluorspar sales (domestic and foreign) to consumers in the United States, 1937–41, compared with 1942, by consuming industries and by sources.

dient in frit; it formerly ranked fourth but dropped to sixth place in 1942. Comparatively small quantities of fluorspar are used in a number of miscellaneous operations, such as production of the finer grades of iron castings, chilled-iron rolls, brass and bronze ingots, nickel and Monel metal, aluminum, magnesium, tin, cement, ferro-alloys, carbon electrodes, rock wool, and calcium carbide and cyanamid; in smelting refractory ores of gold, silver, and copper; as a paint pigment; as a binder for abrasives; in a formula for coating welding rods; as a boiler-cleaning compound; as a flux to deslag high-pressure steam generators; for stripping anodizing racks; as an ingredient in various types of fluxing compounds; and in a special cement used to produce a coating for artificially colored roofing granules for camouflage purposes.

SPECIFICATIONS

The chief commercial grades of fluorspar are metallurgical, ceramic, and acid. The standard chemical specification for metallurgical

Digitized by Google

grade is a minimum of 85 percent calcium fluoride and a maximum of 5 percent silica and 0.3 percent sulfur. However, under pressure of increasing demand and as a result of a change in the ceiling-price structure, metallurgical-grade fluorspar containing less calcium fluoride and more silica is being accepted by many consumers. The standard chemical specification for acid-grade fluorspar is a minimum of 98 percent calcium fluoride and a maximum of 1 percent each of silica and calcium carbonate, but a product containing 97½ percent calcium fluoride and 1½ percent silica is now being accepted by consumers. The specifications for ceramic-grade fluorspar vary widely, but the standard specification is a minimum of 95 percent calcium fluoride and a maximum of 2½ percent silica.

CONSUMPTION AND CONSUMERS' STOCKS

The following tables give data on consumption and consumers' stocks of fluorspar.

Fluorspar (domestic and foreign) consumed and in stock in the United States, 1941–42, by industries, in short tons

Industry	1941		1942		
	Consumption	Stocks at consumers' plants Dec. 31	Consumption	Stocks at consumers' plants Dec. 31	In transit to consumers' plants Dec. 31
Basic open-hearth steel	191,300		217,100		
Electric-furnace steel	18,300	[1] 86,800	25,300	63,400	4,084

Miscellaneous	2,500	[1] 1,200	4,100	1,500	123
	303,600	[1] 108,900	360,800	96,000	5,600

[1] Revised figures.

Consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1938–42

	1938	1939	1940	1941	1942
Production of basic open-hearth steel ingots and castings, long tons	25,868,000	43,368,000	55,038,000	[1] 66,056,000	67,821,000
Consumption of fluorspar in basic open-hearth steel production, short tons	73,600	116,200	143,800	191,300	217,100
Consumption of fluorspar per ton of steel made, pounds	5.7	5.4	5.2	5.8	6.4
Stocks of fluorspar on hand at steel plants at end of year, short tons	55,000	69,900	79,800	84,200	60,400

[1] Revised figures.

The quantity of fluorspar used per long ton of basic open-hearth steel varies with each plant, each operator, each furnace, and each heat but probably ranges from less than 1 to 80 pounds. The average for all plants is generally 5 to 8 pounds—a relatively small proportion of the furnace charge. From 1921 (the first year for which these data were collected) to 1940 the average consumption of fluorspar per

Digitized by Google

long ton of steel made declined almost steadily from 8.2 to 5.2 pounds. However, it increased to 5.8 pounds in 1941 and further to 6.4 pounds in 1942—the highest since 1935. The gain in 1941 and 1942 was due partly to the manufacture of proportionately more armor steel, a poorer quality of scrap, higher charges of lime, and rushing of heats. Although electric-furnace steel plants are small users of fluorspar compared with basic open-hearth steel plants, the average consumption (13.5 pounds in 1942) is substantially greater.

PRICES

On January 20, 1942, the Office of Price Administration requested producers of fluorspar "not to publish or quote prices on, nor sell your fluorspar at prices above your prices in effect on January 2, 1942." On January 2 the general price range for standard fluxing gravel fluorspar in the Illinois-Kentucky district was $23 to $25 a short ton f. o. b. mines. Inasmuch as production of fluxing gravel fluorspar did not pace consumption, the Office of Price Administration deemed a price increase to be essential to stimulate production and to encourage new producers to enter the fluorspar field. Consequently, new base ceiling prices for metallurgical-grade fluorspar, which became effective November 23 and ranged from $25 to $28 a ton, according to calcium fluoride and silica content, were established in Maximum Price Regulation 126 (Fluorspar), issued November 17, 1942. At the same time, dollar-and-cents ceiling prices were established for acid-grade fluorspar, except in the Illinois-Kentucky field. The following excerpts are quoted from Maximum Price Regulation 126:

(a) Metallurgical grade. (1) The maximum price f.o.b. a consumer's plant on any shipment shall be the price for the effective CaF_2 content as listed in the following table, plus either (i) railroad freight on such shipment from the producer's shipping point to the consumer's plant, or (ii) railroad freight on such a shipment from Rosiclare, Ill., to the consumer's plant, whichever is lower.

Effective CaF_2 content	Base price per short ton
70 percent or more	$28.00
65 percent but less than 70 percent	27.00
60 percent but less than 65 percent	26.00
Less than 60 percent	25.00

(2) The maximum price f.o.b. a producer's railroad or waterway shipping point shall be his maximum delivered price as determined under subparagraph (1) less freight from such shipping point to the consumer's plant.

(3) The effective CaF_2 content shall be determined by deducting 2½ times the SiO_2 content from the CaF_2 content.

(b) Acid-grade fluorspar produced outside the Illinois-Kentucky fluorspar district. (1) The maximum price f.o.b. a consumer's plant for any shipment of acid-grade fluorspar with a minimum of 97½ percent CaF_2 and a maximum of 1½ percent SiO_2 shall be $32.00 per ton, plus either (i) railroad freight on such shipment from the seller's shipping point to the consumer's plant or (ii) railroad freight on such a shipment from Rosiclare, Ill., to the consumer's plant, whichever is lower.

(2) The maximum price f.o.b. a producer's railroad or waterway shipping point for such acid-grade fluorspar shall be his maximum delivered price as determined under subparagraph (1) less freight from such shipping point to the consumer's plant.

The Office of Price Administration on November 28, 1942, exempted fluorspar ore (milling grade) from price control in Amendment No. 42 to Supplementary Regulation No. 1 to the General Maximum Price Regulation, effective November 23, 1942. Ceiling prices previously were the highest charged during March 1942.

Digitized by Google

STOCKS AT MINES OR SHIPPING POINTS

According to reports of producers, the quantity of fluorspar in stock at mines or shipping points at the close of 1942 totaled 51,610 tons, or 29 percent less than in 1941. These stocks comprised 19,429 tons of finished fluorspar and 32,181 tons of crude fluorspar (calculated to be equivalent to 14,000 tons of finished fluorspar).

Stocks of fluorspar at mines or shipping points in the United States, December 31, 1941 and 1942, by States, in short tons

State	1941			1942		
	Crude [1]	Finished	Total	Crude [1]	Finished	Total
Arizona	30		30	30		30
California	150		150	150		150
Colorado	666	434	1,100	3,601	1,067	4,668
Illinois	23,711	19,966	43,677	10,521	13,984	24,505
Kentucky	12,579	10,981	23,560	1,774	3,970	5,744
New Mexico	2,539	425	2,964	15,605	312	15,917
Texas		43	43			
Utah	525	110	635	500	96	596
Washington		38	38			
	40,200	31,997	72,197	32,181	19,429	51,610

[1] The greater part of this crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.

TECHNOLOGIC DEVELOPMENTS

To meet the large and increasing demand for acid-grade fluorspar, several new flotation plants were completed during 1942, the capacity of some existing plants was enlarged, and two new plants were being constructed. New plants were completed and put into operation near Jamestown, Colo., by Harry M. Williamson & Son and the General Chemical Co.; near Salida, Colo., by the Fluorspar Processing Co. and Kramer Mines (Inc.); and at Elizabethtown, Ill., by James W. Patton & Sons. Near Smithland, Ky., Butler & Moodie added a 3-cell flotation machine to its milling plant. The flotation plants of the Aluminum Ore Co. and Rosiclare Lead & Fluor Spar Mining Co. at Rosiclare, Ill., of the Indian Metals Co. at Lordsburg, N. Mex., and of P. L. Grattan at Deming, N. Mex., were enlarged. New plants were being constructed at Los Lunas, N. Mex., by the Zuñi Milling Co., and near Marion, Ky., by the Corod Minerals Co.

Output of flotation concentrates gained phenomenally in 1942, amounting to 106,974 short tons compared with 64,627 tons in 1941.

Experimental work was done on the Heavy-Media Process for separating fluorspar from gangue material. This work proved encouraging, and the installation will be made by the Rosiclare Lead & Fluor Spar Mining Co. in 1943. In applying this process ferrosilicon is used as the heavy medium. The Mahoning Mining Co. is adding to its flotation plant, enabling the company to mill high-barite ore.

FLUORSPAR INDUSTRY IN 1942, BY STATES

Arizona.—Production in Arizona came from mines and prospects in Greenlee and Pima Counties; that from Greenlee County was shipped to flotation plants at Deming and Lordsburg, N. Mex. The flotation concentrates recovered from the fluorspar, rather than the run-of-mine material, have been credited in the statistics to Arizona. The fluorspar from Pima County was produced at the Fluxore

Digitized by Google

Claims by N. A. Gonzales and shipped to steel plants and iron foundries on the West coast. The property discontinued operating in April 1942.

California.—The Industrial Minerals & Chemical Co. shipped a small quantity of ground fluorspar during 1942. This company has a plant at West Berkeley, where fluorspar from Nevada is ground. The fluorspar is credited in the statistics to Nevada.

Colorado.—The reopening of mines in Boulder and Jackson Counties and greatly accelerated production at mines in Chaffee County are reflected in the shipment of 31,743 short tons of fluorspar from Colorado in 1942 compared with 15,566 tons in 1941. Shipments in 1942, however, were 17 percent less than the all-time high established by Colorado in 1918. Of the 1942 shipments, 56 percent went to steel plants, 30 percent to hydrofluoric-acid plants, 8 percent to glass and enamel plants, and the remaining 6 percent to iron foundries, welding-rod manufacturers, and aluminum, magnesium, ferro-alloy, and cement plants.

Production in Colorado in 1942, which amounted to 33,400 tons, came from Boulder, Chaffee, Jackson, and Mineral Counties, but mines in Chaffee County supplied 47 percent of the State total.

The flotation mill of Harry M. Williamson & Son near Jamestown made its initial production of concentrates in March 1942; the ore treated in the mill came from the company Emmett mine in Boulder County. At its Brown Spar mine, also in Boulder County, the shaft was sunk to 300 feet and a heavier hoist installed. The General Chemical Co., which acquired the Chancellor, Yellow Girl, and Burlington mines in Boulder County in 1940, acquired the Alice mine, also in Boulder County, in 1942. These mines furnish ore for the company flotation mill near Jamestown, which began production in May 1942. This company also operates a flotation mill in New Mexico. The American Fluorspar Corporation made a substantial increase in production at its mine near Salida (Chaffee County), did considerable development work, electrified the mine, and began opening a mine at Poncha Springs in the same county. The flotation mill of the Fluorspar Processing Co., on property of the American Fluorspar Corporation, began operating in April 1942; the ore milled is supplied by the American Fluorspar Corporation. The Colorado Fluorspar Corporation reported gains over 1941 of 24 and 86 percent, respectively, in production of metallurgical-grade and flotation concentrates. A shaft was sunk to the 118-foot level, and a 100-foot tunnel was driven along a newly found ore body. The flotation mill of Kramer Mines, Inc., near Salida, began operating in October 1942. Ore for the mill comes from the company mine, also near Salida. The Western Feldspar Milling Co., Denver, shipped 8 percent more ground fluorspar to the glass trade in 1942 than in 1941. The ore ground by this company is supplied by the American Fluorspar Corporation. The Western Fluorspar Corporation spent the latter part of 1941 and the first half of 1942 rehabilitating the long-idle mine near Northgate, Jackson County, and remodeling and enlarging the mill. Production was begun on July 15, 1942, and continued until December 10, when a fire destroyed the mill; it is now being rebuilt. The Wagon Wheel Gap mine, of the Colorado Fuel & Iron Corporation in Mineral County, was inactive in October because the concentrating mill was being remodeled; in consequence, production was 8 percent less than in 1941.

Digitized by Google

Illinois.—Approximately 282,000 short tons of fluorspar-bearing material, equivalent to 145,000 tons of finished fluorspar, were mined in 1942 compared with 248,000 tons, equivalent to 135,000 tons of finished fluorspar, in 1941. Of the finished fluorspar produced in 1942, it is estimated that about three-fifths was from vein deposits and two-fifths from bedded deposits. Of the fluorpsar produced in Illinois in 1942, about 95 percent came from Hardin County and 5 percent from Pope County.

Fluorspar-bearing material milled in 1942 totaled 296,000 tons, from which about 156,000 tons of finished fluorspar were recovered—a ratio of 1.9:1. Considerable Kentucky fluorspar is milled in Illinois, and some Illinois fluorspar is milled in Kentucky; the finished fluorspar so recovered, as well as that shipped, is credited in the statistics to the State of origin.

Shipments from Illinois (161,949 tons) in 1942, which established a new record, were 21 percent more than in 1941 and 3.4 percent greater than in 1917, the previous record year. The 1942 shipments comprised 77,947 tons to steel plants, 62,573 tons to hydrofluoric-acid plants, 7,520 tons to glass and enamel plants, 7,155 tons to Canada and Peru, and 6,754 tons to iron foundries, nonferrous smelters, aluminum- and magnesium-reduction plants, and ferro-alloy, nickel, and welding-rod manufacturers. Of the 1942 total, 42,250 tons were shipped by river or river-rail to consumers compared with 39,918 tons in 1941.

The Air Shaft-Midway-North Boundary, Argo, Blue Diggings, Crystal, A. L. Davis, W. L. Davis, Deardorff, W. C. Green, Hillside, Humm, Lead Hill, North Daisy, Roberts, Rosiclare, Stewart, and Victory mines supplied about 87 percent of the total finished fluorspar produced in Illinois in 1942; the remainder came from many mines and prospects, including the Austin, Big Creek, Cave in Rock, Cooper, Crabb, Douglas, Du Bois, Eureka No. 4 and No. 5, Good Hope, Hamp, Hanson, J. W. Hill, Last Chance, Lost 40, Love, Pell, Red Tipple, Rose Creek, South Boundary, Wall, and Winn.

The Fluorspar Products Co. operated the Lead Hill and Stewart mines and also milled purchased ore from various properties. Shipments were 8 percent less than in 1941. Two shafts were sunk on the Stewart property. A core drill was operated about 9 months.

The Aluminum Ore Co. produced 95 percent more fluorspar at its flotation plant in 1942 than in 1941. The mill feed comprised ore from the company Argo, Blue Diggings, Good Hope, Hamp, Hanson, and Last Chance mines and a small quantity of purchased ore. Additional flotation cells and drying and grinding equipment were added to the mill in 1942, doubling its capacity. The company was active sinking shafts in 1942. Its Fairview shaft, on the Argo-Blue Diggings veins, has been sunk to the 700-foot level; it is being sunk an additional 90 feet and will be the largest shaft in the fluorspar district, being 12 by 12 feet cross section in the clear. Three smaller shafts have been sunk along the same veins to the 300-foot level; these shafts were required to supply the immediate demand for crude material, and each was brought into production during the latter part of 1942.

Production at the Crystal mine of the Crystal Fluorspar Co. was slightly less than in 1941. Considerable output was lost as a result of two strikes. Prospecting and development work included 17,211 feet of churn and diamond drilling at the Crystal mine and 935 feet of churn drilling along the Crystal-Mahoning east-west property line.

556250—43——89

Digitized by Google

Hillside Fluor Spar Mines purchased the Dimick property, adjoining the Hillside property on the northwest, and has rehabilitated the shaft to the 200-foot level. Workings are being carried forward on two prominent ore bodies to develop them for production. Exploration work is being done by drilling in cooperation with the Illinois Geological Survey, which also has been doing some geophysical work. Production of gravel fluorspar and flotation concentrates by Hillside Fluor Spar Mines was 7 and 4 percent, respectively, less than in 1941. The mill feed came from the Dimick, Hillside, and Wall mines in Illinois and the Keystone mine near Marion, Ky.

The Rosiclare Lead & Fluor Spar Mining Co. operated the Daisy, Eureka No. 4 and No. 5, Midway-North Boundary-Air Shaft, North Daisy, Rosiclare, and South Boundary mines in 1942, but the North Boundary and Rosiclare mines were the chief producers. Production at the gravity concentrating mill was 5 percent less than in 1941. Output at the flotation plant, however, was 89 percent more than in 1941. Shipments of fluorspar of all grades were 33 percent greater than in 1941. The flotation mill was enlarged during 1942. Experimental work was done on the Heavy-Media Process for separating fluorspar from gangue material. This work proved encouraging, and the installation will be made in 1943. In applying this process ferrosilicon is used as the heavy medium. The company pushed development work in all its mines and did considerable surface and underground drilling. Development work was under way on the 600- and 700-foot levels of the Rosiclare mine, and considerable prospecting was done on an outlying property.

The Victory mine of the Victory Fluorspar Mining Co. was operated at about the same rate as in 1941. A diamond-drilling program was carried on during the summer and fall without any notable finds.

The Cave in Rock Spar Co. remodeled its mill and did some development work at its mining properties. Most of the ore milled in 1942 was purchased from local producers. Production of finished fluorspar, however, was substantially less than in 1941.

The flotation mill of the Mahoning Mining Co. produced 28 percent more fluorspar concentrates than in 1941. The mill feed comprised ore from the A. L. Davis, W. L. Davis, Deardorff, and W. C. Green mines and a small quantity of purchased ore. Production of finished fluorspar comprised 86.4 percent acid grade and 13.6 percent pelletized gravel. During 1942 a new shaft (the East Green) was completed to develop an ore body, and the A. L. Davis and West Green ore bodies were opened. At the flotation plant, improvements are in progress to enable the mill to handle high-barite ore and to increase capacity to some extent. The motors in the flotation mill [3] and the new Diesel generating unit at the W. L. Davis mine [4] have been described by Edwards.

Jas. W. Patton & Sons treated tailings from the Crystal mine in its flotation plant near Elizabethtown.

The Humm mine was operated by C. C. Mackey during the first 9 months of 1942, then it was worked by Barnett, Karber & Adams. Output by all operators was at about the same rate as in 1941.

The Yingling Mining Co. did considerable development work and produced a small quantity of fluorspar at the Nicholas Hamp and

Digitized by Google

Rose Creek mines. It remodeled a mill formerly run by the Big Creek Fluorspar Co., which discontinued operations in March 1942. The mill includes air tables and electrostatic separation to produce fluorspar, lead, and zinc concentrates.

A new operator, the Minerva Oil Co., is developing a mine near Cave in Rock and expects to get into production the latter part of 1943. A shaft is being sunk to a depth of 630 feet, and a flotation plant to produce fluorspar and zinc concentrates is planned.

Production at the Roberts mine in Pope County, operated by Roberts & Frazer of Illinois (Kentucky Fluor Spar Co. affiliate) more than tripled that in 1941. This mine is equipped with log washer, picking belt, and screens.

Kentucky.—Production of fluorspar (expressed in terms of finished product) in Kentucky was about 121,500 short tons in 1942 compared with 135,500 tons in 1941. Shipments were 134,133 tons in 1942, a decline of 6 percent from the all-time record of 1941. The 1942 shipments comprised 111,370 tons to steel plants, 11,141 tons to glass and enamel plants, 4,576 tons to hydrofluoric-acid plants, 1,750 tons to Canada, and 5,296 tons to iron foundries, nonferrous smelters, and cement, ferro-alloy, and aluminum-reduction plants. Of the 1942 total, 36,799 tons were shipped to consumers by river or river-rail compared with 34,698 tons in 1941.

Production in Caldwell County came chiefly from the Hollowell & Hobby, Hughett, Marble, Senator, and Tyrie (Lester) mines.

John Hughett completed a shaft at his mine near Princeton and began production in 1942.

Production at the Hollowell & Hobby mine, operated by the New York & Kentucky Mining Co., was about 25 percent less than in 1941. The company did much prospecting but did not locate any extensive ore bodies.

Core drilling by W. H. Crider disclosed a productive ore body at the Senator mine, and a shaft was sunk and machinery installed. The mine was sold to the Midland Minerals Corporation in December 1942.

Various operators produced fluorspar at the Marble mine of the S. L. Crook Corporation during 1942.

About 90 percent of the production in Crittenden County came from the Bachelor, Davenport, Keystone, Pigmy, Summers, Tabb, Waddell, and Watson (Eagle) mines. Most of the remainder came from many smaller mines (including the Barnes, Blue, Brown, Butler, Corn, Crystal, Dyke, Gilless, Haffaw, Hodge, Krause, Madry, Memphis, Pogue, Redd, Reiter, Simpkins, Sullinger, and Watkins) and from numerous prospects; some was reclaimed from waste dumps and old workings of abandoned mines.

The Eagle Fluor Spar Co. produced 17 percent more fluorspar at its Watson mine than in 1941. The 1942 production comprised 74 percent of metallurgical grade and 26 percent of acid grade. Perry & Loyd reworked the Watson tailings and recovered considerable fluorspar.

The mill of R. J. Forester handled ore from his Summers mine and some purchased ore, recovering about the same quantity of finished fluorspar as in 1941.

The Tabb mines and mill of the United States Coal & Coke Co. produced 8 percent more finished fluorspar than in 1941; shipments were 40 percent greater. The company did considerable development work and made improvements in its mill during 1942.

Digitized by Google

The Kentucky Fluor Spar Co., which operates a mill a short distance south of Marion, did the largest volume of business in its history; tonnage and dollar sales were 14 and 31 percent, respectively, greater than in 1941. In 1942 the company, through its mining division (Roberts & Frazer), operated the C. R. Babb, Carr, and Ellis mines in Livingston County, Ky., and the Roberts mine in Pope County, Ill.; about two-thirds of the company supply came from these mines, and the remainder chiefly from the Barnes, Nancy Hanks, and Waddell mines in Kentucky.

At the Keystone mine of Hillside Fluor Spar Mines a new deep-well pump, operated by direct-connected Diesel engine and capable of handling 1,000 gallons of water a minute against a 600-foot head, was installed in 1942. With this equipment it is hoped to keep the lower levels unwatered during the heavy-rain season and to extend the workings at least to the 600-foot level. A new shaft (No. 4) was sunk to 300 feet and encountered good ore. The workings of this shaft will be connected with other mine workings to the north to give additional tramming and hoisting facilities. Production at the Keystone mine was considerably less than in 1941. Although the fluorspar from this mine is finished at the company mill at Rosiclare, Ill., production and shipments are credited in the statistics to Kentucky.

Production at the Pigmy mine of the Pigmy Corporation (subsidiary of the Rosiclare Lead & Fluor Spar Mining Co.) was 19 percent less than in 1941. Development work at the Pigmy mine consisted chiefly of shaft sinking, drifting, and diamond drilling.

Development work at the Davenport mine consisted of locating an unknown ore body by drilling and of driving a crosscut to it. A new shaft to cut the extension of this ore body is contemplated. A new 6-cell coarse jig was added to the mill. Production was about 21 percent less than in 1941. The mineral right and some surface at the Davenport mine were purchased December 31, 1942, by the National Fluorspar Co., which previously operated the mine under lease.

In 1942 the Delhi Fluorspar Corporation continued development work at its Bachelor mine and plans to sink a 600-foot shaft in early 1943. Production was substantially less than in 1941. However, the 1942 deficit in production was made up with purchased fluorspar; as a consequence, shipments from Kentucky were greater than in 1941.

The Howard Easley Corporation, which operates a custom mill near Marion, worked two shifts during part of 1942 and as a result milled considerably more ore than in 1941. In the mill a second crusher was added and many improvements were made to increase production.

In Livingston County the bulk of the fluorspar produced came from the C. R. Babb, Carr, Ellis, Nancy Hanks, and Wright mines, from C. R. Babb and Nancy Hanks tailings, and from the jig reclaiming plant working Klondike tailings.

Output at the C. R. Babb, Carr, and Ellis mines of Roberts & Frazer was 31 percent greater than in 1941. Edwin W. Frazer reworked the tailings at the C. R. Babb mine and recovered 380 tons of fluorspar.

The levels in the Nancy Hanks mine, operated by W. V. Haynes, Jr., were retimbered during 1942, causing some loss in production. Nevertheless, output of finished fluorspar was 7 percent more than in 1941. Tinsley & Loyd reclaimed a substantial quantity of fluorspar from Nancy Hanks tailings.

Digitized by Google

Butler & Moodie, operating a jig plant reclaiming fluorspar from Klondike-mine tailings, recovered about half as much fluorspar from that source as in 1941. Some ore was also milled for John Hughett. A 3-cell flotation machine was installed during January 1943.

As the result of an increase in price and a change in the specification for metallurgical-grade fluorspar, Ralph E. Jones has reopened the Faircloth mine in Woodford County near Wilmore and has remodeled the mill. The ore in this mine is impregnated with considerable calcite and is difficult to mill to 85 percent calcium fluoride. However, it is associated with but little silica and is therefore amenable to a product containing 70 percent effective calcium fluoride. A small production was made in 1942.

Nevada.—Shipments of fluorspar from Nevada in 1942—8,020 short tons—were 11 percent less than the all-time record of 8,967 tons in 1941. Most of the 1942 total went to steel mills and hydrofluoric-acid plants.

The chief producing mine in Nevada in 1942 was the Baxter in Mineral County, operated by V. S. Baxter; production was about the same as in 1941. The other active mine was the Daisy in Nye County, operated by J. Irving Crowell, Jr.; production was 25 percent less than in 1941.

New Mexico.—Production of fluorspar in New Mexico, which established a new record in 1942, came from Catron, Dona Ana, Grant, Luna, Sierra, and Valencia Counties.

Shipments from New Mexico, Arizona, and Texas totaled 23,291 short tons compared with 19,089 tons in 1941. Of the 1942 shipments, slightly more than half was of metallurgical grade, which moved to steel mills and iron foundries; the remainder was chiefly flotation concentrates, which were shipped mainly to hydrofluoric-acid and glass plants.

The gravity-flotation mill of the Non-Metallic Corporation at Silver City was operated by the Continental Chemical & Ore Co. during part of 1942; the concentrates produced were shipped to a hydrofluoric-acid plant. The mill feed comprised chiefly purchased ore from the Clum mine in Grant County; a small amount came from the Huckleberry mine in Catron County, operated by the company.

The Diamond mine (formerly Tortugas) near Mesilla Park, Dona Ana County, is being reopened by Jacques K. Stanland. The shaft was extended 300 feet farther, about 1,500 feet of lateral work were done, a railroad connection was built to the mine, and a gravity-concentration mill was expected to be completed in early spring. In the course of development work, some milling-grade ore was produced and shipped to a local flotation plant.

The flotation mill of the Indian Metals Co. at Lordsburg was operated at a substantially reduced rate in 1942. The ore milled was purchased from many properties, but the greater part came from the Howard and Sanders mines in New Mexico and the Ellis (Fourth of July No. 2) mine in Arizona. The Indian Metals Co. practically rebuilt its mill, doubling capacity, in 1942, recently began development work at two mines in Hidalgo County, and plans to develop two additional mines in the same county.

P. L. Grattan's remodeled flotation mill at Deming resumed production in 1942. A new bank of cells was added, and changes and improvements were also made. At the Grattan mine in Luna County

Digitized by Google

the shaft was straightened, and a head frame, surface houses, and a road were built.

The Lucky and Greenleaf No. 4 mines in Luna County have been under development since October 1942 by the Western Mining Corporation. The Lucky mine made its initial production in January 1943.

The Howard and Sadler mines in Luna County were important producers during 1942.

The flotation mill of the General Chemical Co. at Deming was operated on a substantially larger scale than in 1941. This company also operated the Spar Group and Sadler mines in Luna County and the Osmer (Shrine) mine in Grant County; the last two mines were acquired in 1942. In addition to the production from its own mines, considerable milling-grade ore was purchased from various producers in Arizona, New Mexico, and Texas.

Since May 1942 Kinetic Chemicals, Inc. (du Pont subsidiary), has carried on development work at its Lyda K mine near Arrey, Sierra County. As of December 31, a new 100-foot shaft had been sunk at the north end of the vein, and a 150-foot drift to the northeast and a 175-foot drift to the southwest had been driven at that level. A new hand-sorting mill, under construction, is expected to be in operation by April 1943 at an annual rate of 10,000 tons. Production is expected to comprise about 15 percent of acid grade, 50 percent of metallurgical grade, and 35 percent of mill-feed grade.

The Navajo mine in Valencia County, operated by Navajo Fluorspar Mines, produced 65 percent more finished fluorspar than in 1941. In addition, a substantial tonnage of ore was produced for mill feed at the flotation mill being constructed at Los Lunas (N. Mex.) by the Zuñi Milling Co., affiliate of Navajo Fluorspar Mines. This mill is expected to be brought into production during 1943.

Development work was done and considerable fluorspar produced during 1942 at the Bonita and Breece mines in Valencia County by the Both Mining & Milling Co.

Small outputs were made at the Mirabal and Keeney properties, also in Valencia County.

Tennessee.—The Foley mine in Smith County near Rome was reopened in 1942 and a small quantity of metallurgical-grade fluorspar was produced and shipped by Frailey & Heap.

Texas.—A small tonnage of milling-grade ore was produced at the Horse Shoe prospect near Hot Wells, Hudspeth County, by U. B. Melton; it was shipped to a flotation plant at Deming, N. Mex.

Utah.—Shipments of fluorspar from Utah in 1942 were 1,018 short tons (an all-time high) compared with 748 tons in 1941.

The Western Fluorite Co., which has done considerable development work at many properties in Beaver County and completed a mill near Milford, was the chief producer in Utah in 1942. The Staats mine, also in Beaver County, operated by Fred Staats, produced substantially less fluorspar than in 1941, chiefly because of a shortage of labor.

The Cougar mine near Milford in Beaver County was being developed by the Tintic Standard Mining Co. in 1942.

Washington.—A small quantity of fluorspar, mined in 1941, was shipped from the Mitchem mine in Ferry County by the Mineral Products Co. in 1942.

Digitized by Google

FOREIGN TRADE

Imports.—Imports of fluorspar for consumption in the United States during 1942 were 2,151 short tons (1,882 tons containing more than 97 percent and 269 tons containing not more than 97 percent calcium fluoride), valued[5] at $35,529, compared with 7,524 tons (1,516 tons containing more than and 6,008 tons not more than 97 percent calcium fluoride), valued [5] at $80,135. The value assigned to the higher-grade foreign fluorspar averaged $19.69 and $16.98, respectively, in 1941 and 1942, and that of the lower-grade $8.37 and $13.30, respectively. The cost to consumers in the United States also includes duty, loading charges, insurance, consular fee, and freight to consuming plants.

Fluorspar imported for consumption in the United States, 1941–42, by countries [1] and customs districts

[1] For historic table, see Minerals Yearbook, 1941, p. 1401.
[2] Less than 1 ton.

The following table, compiled from data furnished to the Bureau of Mines by importers, shows the quantities of imported fluorspar delivered to consumers in the United States in 1941 and 1942 and the selling price at tidewater (duty paid), irrespective of the year of importation into the United States; it differs from the preceding table, which shows the quantities received in the United States during 1941 and 1942. The quantities in the following table are based upon the actual outturn weights ascertained by sworn weighers and represent the weights on which duty was paid and entries were liquidated.

[5] As defined in sec. 402 of the tariff act of 1930, "The value of imported merchandise • • • is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the merchandise in condition ready for shipment to the United States."

[1] Estimated.

Exports.—Producers of fluorspar reported exports of 9,016 short tons of fluorspar valued at $242,545 in 1942 compared with 12,184 tons valued at $277,782 in 1941. The exports in 1942 by producers comprised 1,714 tons of fluxing gravel, 557 tons of ceramic ground, 4,899 tons of acid grade, and 1,616 tons of special-grade (96 percent CaF_2) jig concentrates, all to Canada, and 230 tons of ceramic ground to Peru. In addition to the fluorspar exported by producers in 1942, brokers reported exports of 4 tons of ceramic ground—3 to Chile and 1 to Uruguay.

Fluorspar reported by producers as exported from the United States, 1938–42

Year	Short tons	Value		Year	Short tons	Value

1938	788	$9,061	$11.50	1941	12,184	$277,782	$22.80
1939	2,976	74,443	25.01	1942	9,016	242,545	26.90
1940	8,482	178,467	21.04				

Tariff reduction.—The trade agreement between the United States and Mexico, signed December 23, 1942, and proclaimed by the President December 28, provided for a duty of $6.30 a long ton ($5.625 a short ton) on fluorspar containing not more than 97 percent calcium fluoride imported into the United States. The former duty was $8.40 a long ton ($7.50 a short ton). The duty on fluorspar containing more than 97 percent calcium fluoride remained at $4.20 a long ton ($3.75 a short ton).

WORLD PRODUCTION

The following table shows world production of fluorspar by countries from 1937 to 1942, insofar as statistics are available. Because of restriction on the publication of statistics by the governments of many countries, few figures for 1940, 1941, and 1942 are available.

[1] In addition to countries listed, China and Mexico produce fluorspar but data of output are not available.
[2] Data not available.
[3] Exports.
[4] Estimated.
[5] January to September, inclusive.
[6] Estimate included in total.
[7] January to June, inclusive.

Argentina.—Production of fluorspar in Argentina increased markedly to 2,234 short tons in 1941 from 658 tons in 1940.

Brazil.[6]—The Companhia Brasileira de Alumino controls a promising, newly discovered fluorspar deposit in the southern edge of the sulfide belt of Ribeira de Iguapa Valley. Before this discovery, only minor occurrences of fluorspar were known in the country.

Canada.—Production of fluorspar in Canada has been relatively small in recent years but in 1941 amounted to 5,534 short tons. This output, however, falls far short of consumption; consequently, search for deposits has been under way. The greater part of the fluorspar consumed in Canada is imported from Newfoundland and the United States.

Mexico.—Production figures on fluorspar in Mexico in 1942 are not available, but 5,914 short tons were exported in that year compared with exports of 11,597 tons in 1941 and 10,220 tons in 1940. Most of the fluorspar exported in 1940 and 1941 went to Japan. Before the war the La Azul mine at Taxco, Guerrero, largest producer of fluorspar in Mexico, was under Japanese control; it has since been taken over by the Enemy Property Custodian, who has called for bids to operate the mine. When production is resumed, a substantial increase in output can be expected.

Digitized by Google

Newfoundland.—Production of fluorspar in Newfoundland in 1942 is reported to have reached 36,000 short tons.[7] Efforts are being made to increase this output, and it is hoped that production in 1943 will reach 100,000 tons.

Fluorspar is produced in Newfoundland by the St. Lawrence Corporation of Newfoundland, Ltd., and Newfoundland Fluorspar, Ltd., the latter a subsidiary of the Aluminum Co. of Canada, Ltd. Production and shipments by the St. Lawrence Corporation of Newfoundland, Ltd., were 12 and 9 percent, respectively, greater in 1942 than in 1941. The 1942 shipments went to Canadian consumers and comprised 15 percent acid grade, 74 percent metallurgical grade, and 11 percent crude (65 percent CaF_2). The St. Lawrence Corporation of Newfoundland, Ltd., completed a flotation plant late in 1942. Newfoundland Fluorspar, Ltd., which has been doing exploration and development work for several years, began producing in 1942. After hand-picking and crushing at the mine the output, which contains 70 to 80 percent calcium fluoride, is shipped to Arvida, Canada, where the Aluminum Co. of Canada, Ltd., has a flotation plant to mill the ore to acid grade.

Sweden.—For some time explorations have been made regarding possibilities of mining fluorspar at the Branteviks mines in the Province of Skåne in south Sweden. Deposits were discovered near the surface, and test borings have now reached a depth of 50 to 60 meters (164 to 197 feet). Machinery to permit further operations has been ordered.[8]

Aktiebolaget Branteviks Gruvor has begun mining fluorspar on a small scale; the material is to be used in manufacturing light metals in a plant at Sundsvall.[9]

Union of South Africa.—Production of fluorspar in the Union of South Africa was 3,888 short tons during the first 9 months of 1942 (figures for the remaining 3 months not available) compared with about 4,300 tons in the year 1941 and 8,180 tons in 1940.

CRYOLITE

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland. Gibbs[10] has described the mine at Ivigtut, grades of ore produced, methods of processing and purification, and various uses of cryolite.

A sizable proportion of the cryolite used in the United States is made from fluorspar. According to Frary:[11]

> The fluorspar is treated with sulfuric acid to produce hydrofluoric acid, and this is neutralized with the proper amounts of soda ash and aluminum hydrate to produce the cryolite, which is a double fluoride of sodium and aluminum (Na_3AlF_6). The artificial cryolite is quite satisfactory and, in fact, considerably lower in objectionable impurities than the natural cryolite usually used. There would be no serious difficulty in getting along with the artificial product if the supply of natural cryolite from Greenland is shut off.

The chief use of cryolite is in the metallurgy of aluminum; comparatively small amounts are used in glass, enamels, abrasives, and insecticides.

Digitized by Google

Cryolite was put under complete allocation and use control by General Preference Order M–198, issued by the War Production Board September 18, 1942. Cryolite, both natural and artificial, could not be delivered, received, or used after October 1, 1942, except by specific authorization of the War Production Board. The sole exception to the provision is receipt and use as an insecticide.

Artificial cryolite was manufactured in the United States in 1942 by the Aluminum Ore Co. at East St. Louis, Ill.; this company is building a plant near Bauxite, Ark. A small quantity of artificial cryolite was made in a pilot plant by the Pennsylvania Salt Manufacturing Co. in 1942; it has about completed a commercial plant at Cornwells Heights, Pa.

The following table shows imports of cryolite into the United States in 1941 and 1942.

Cryolite (natural and artificial) imported for consumption in the United States, 1941–42, by countries

SUMMARY

Conversion of many enamel and porcelain plants to the heat treating of steel, to the manufacture of parts or assemblies for war machines, or to other activities more closely allied to successful completion of the war sharply reduced the consumption of feldspar in the enamel and porcelain industries in 1942. Curtailment of plate-glass production also tended to reduce feldspar sales. However, production and shipments of glass containers, which probably represent the most important consumer outlet for feldspar, in 1942 broke all records by increases of 12 and 15 percent, respectively, over 1941, the former record year. Sales of feldspar to glass plants in 1942 were the highest recorded since annual statistics by uses were first compiled (1934) and undoubtedly also the highest in the history of the industry. The 7-percent increase over 1941 in this category, however, was not sufficient to offset the decline in sales to porcelain and enamel manufacturers.

Salient statistics of the feldspar industry in the United States, 1940–42

	1940	1941	1942	Percent of change in 1942
Crude feldspar:				
Domestic sales:				
Long tons	290,763	338,860	307,823	−9.2
Value	$1,271,995	$1,519,456	$1,516,791	−.2
Average per long ton	$4.37	$4.48	$4.93	+10.0
Imports:				
Long tons	12,522	11,253	9,525	−15.4
Value	$80,274	$73,236	$69,797	−4.7
Average per long ton	$6.41	$6.51	$7.33	+12.6
Ground feldspar sold by merchant mills:				
Short tons	285,713	354,417	327,786	−7.5
Value	$3,065,482	$3,782,603	$3,524,969	−6.8
Average per short ton	$10.73	$10.67	$10.75	+.7

Sales of crude spar in 1942 totaled 307,823 long tons, valued at $1,516,791, a decrease of 9 percent in quantity and of 0.2 percent in value from 1941. Sales of ground spar aggregated 327,786 short tons valued at $3,524,969, a decline of about 7 percent in quantity and value from 1941. The output of both crude and ground feldspar in

Digitized by Google

1942, however, was considerably higher than in any year other than 1941. The average value per ton of crude spar rose 10 percent in 1942, while the downward trend in recent years in realization per ton of ground spar was checked and a small increase recorded.

Crude feldspar imported into the United States in 1942 amounted to 9,525 long tons valued at $69,797, a decrease of 15 percent in tonnage and 5 percent in value from 11,253 tons valued at $73,236 imported in 1941.

Most States produced somewhat less crude feldspar than in 1941, notable exceptions being Arizona, California, and Wyoming. In 1942 South Dakota achieved a new high in output (sales) of ground feldspar. Other States grinding more spar than in 1941 were Arizona, California, and Virginia. Somewhat smaller outputs than in 1941 were reported by New Jersey-Connecticut, North Carolina-Tennessee, Maine, and New Hampshire.

DOMESTIC PRODUCTION

Following the usual practice in the industry, crude feldspar is reported in long tons of 2,240 pounds and ground feldspar in short (net) tons of 2,000 pounds.

Crude feldspar.—Crude feldspar sold in 1942 totaled 307,823 long tons, a 9-percent decrease from the record year 1941 but 6 percent above sales in the highest previous year (1940). The total value ($1,516,791) in 1942 was only slightly less than in 1941.

Crude feldspar sold or used by producers in the United States, 1938–42

[Value at mine or nearest shipping point]

Year	Long tons	Value		Year	Long tons	Value	
		Total	Average			Total	Average

Digitized by Google

States producing crude feldspar in 1942 were the same as in 1941, except that no output in 1942 was reported from Maryland or Massachusetts. The four leading States in 1942, in order of production (North Carolina, South Dakota, New Hampshire, and Colorado), reported decreases of output ranging from 4 percent for South Dakota to 21 percent for Colorado. There were substantial percentage increases, however, in California, Virginia, and Wyoming, as well as in Arizona and Texas; production data cannot be shown for the last two. Sales of crude feldspar in 1942 in Connecticut, Maine, and New York were less than in 1941.

The average sales realization per long ton for crude feldspar increased 10 percent over 1941 to $4.93 in 1942 and was the highest reported since 1937. All States for which figures can be given (except California and Wyoming) show higher average values in 1942 than in 1941. Averages per ton for selected States in both years (1941 in parentheses) follow: North Carolina, $5.70 ($5.52); Virginia, $5.77 ($5.58); South Dakota, $3.46 ($2.89); Maine, $6.02 ($5.17); and Colorado, $4.03 ($3.49).

Ground feldspar.—Ground feldspar sold by merchant mills in 1942 decreased 8 percent in tonnage and 7 percent in value, compared with the peak year 1941, and totaled 327,786 short tons valued at $3,524,969. The tonnage in 1942 was 15 percent above that in 1940, the former record year. Sales by North Carolina and Tennessee mills supplied 26 percent of the total ground spar sold, compared with 27 percent in 1941 and 1940 and 32 percent in 1937. Although producing slightly less ground spar in 1942 than in 1941, South Dakota and Colorado combined furnished 37 percent in 1942 compared with 34 percent in 1941 and 30 percent in 1937. Sales of feldspar of Canadian origin ground in United States mills amounted to 3 percent of the total merchant sales in 1942 compared with 2 percent in 1941, 3 percent in 1940, and 6 percent in 1937.

South Dakota sales of ground feldspar rose 14 percent in 1942 to 68,025 short tons (valued at $483,075)—a record tonnage—giving it first place among the producing States. Tennessee ranked second, followed by Colorado, North Carolina, and New Hampshire. States that produced more ground spar than in 1941, in addition to South Dakota, with percentages of increase, were: Illinois, 0.5 percent; Arizona, 24; California, 37; and Virginia, 38 percent. The output from Tennessee and North Carolina combined decreased 10 percent compared with 1941. All other States reported declines in output of ground feldspar ranging from 12 percent for New Jersey and New York and 15 percent for Colorado to 29 percent for Maine and 34 percent for New Hampshire.

Ground feldspar sold by merchant mills [1] in the United States, 1938–42

Year	Active mills	Domestic			Canadian			Total	
		Short tons	Value		Short tons	Value		Short tons	Value

Digitized by Google

The downward trend in recent years in average realization for ground feldspar marketed in the United States was checked, at least temporarily, in 1942 when the average for all ground spar sold rose to $10.75 per short ton compared with $10.67 in 1941 and $10.73 in 1940. The average value of ground spar sold was greater in all States except New Jersey, North Carolina, Tennessee, and Virginia. Percentages of increase in average realization ranged from 2 percent for New York and 10 percent for Arizona and California to 18 percent for New Hampshire. The range of average values for individual States in 1942 was $6.75 to $17.77, somewhat narrower than in 1941 when similar figures ranged from $6.34 to $17.92. Average realizations per ton for selected States in 1942 follow: Colorado, $6.75; South Dakota, $7.10; California, $13.07; North Carolina-Tennessee, $12.04; Maine, $14.70; and New Jersey (including marketed spar ground in Connecticut), $17.77.

According to Engineering and Mining Journal, Metal and Mineral Markets, quotations on ground feldspar during 1942 remained the same as in 1941. Potash spar in Maine and North Carolina, 200-mesh, white, in bulk, was quoted at $17 per short ton, f. o. b. mill; and soda spar, similarly prepared, at $19. North Carolina granular glass spar, 20-mesh, white, in bulk, f. o. b. mill, brought $12.50 per ton, with semigranular spar quoted at $11.75. Virginia quotations, as listed in the same journal, were: No. 1, 230-mesh, $18; 200-mesh, $17; glassmakers' spar, No. 17, $11.75, and No. 18, $12.50. Enamelers' spar, either on Spruce Pine, N. C., or Keene, N. H., basis, was quoted at $14 to $16 per ton.

CONSUMPTION AND USES

Crude feldspar.—Most crude feldspar is sold to merchant mills, which obtain their supply from a number of mines or localities. The raw spar is stock-piled and sorted according to grade and source, then blended and ground to specified purity and fineness and sold to ultimate consumers. However, a few pottery and enamel manufacturers have purchased part or all of their feldspar requirements crude and

Digitized by Google

have ground it as needed in their own mills. Makers of soap, cleansers, and sweeping compounds also mine or purchase crude feldspar, largely from New England, Virginia, and North Carolina, and after grinding or otherwise processing it utilize the abrasive properties of the spar in their products. Manufacturers of artificial teeth annually use a small tonnage of carefully selected crude material, which must be free from all grit and is sold at a substantial premium over No. 1 grade commercial feldspar.

Ground feldspar.—The ceramic industry uses well over 95 percent of the ground feldspar sold by merchant spar mills each year in the United States. Most of the spar, by far, is consumed in the glass, pottery, and enamel trades. The glass industry increased its share of feldspar used to 195,601 short tons or 60 percent of the total ground spar sold, compared with 52 percent in 1941. Sales of spar for use in pottery and in enamel fell sharply in 1942, each outlet having dropped approximately 20,000 tons from 1941; pottery decreased from 36 to 32 percent of the total marketed spar and enamel from 10 to 4 percent. The remainder of the ground feldspar sold by merchant mills was utilized for various ceramic uses other than glass, pottery, and enamel; for soaps and abrasive purposes; and for purposes not specified. Minor uses of feldspar include its employment as a welding-rod coating,[1] and as a cementing material in laying firebrick walls.

Ground feldspar sold by merchant mills in the United States, 1940–42, by uses

Use	1940		1941		1942	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Ceramic:						
Glass	149,623	52.4	182,878	51.6	195,601	59.7
Pottery	104,586	36.6	127,140	35.9	106,081	32.4
Enamel	26,420	9.3	34,841	9.8	13,899	4.2
Other ceramic uses	649	.2	563	.2	6,459	2.0
Soaps and abrasives	2,682	.9	1,490	.4	4,396	1.3
Other uses	1,753	.6	7,505	2.1	1,350	.4
	285,713	100.0	354,417	100.0	327,786	100.0

The destinations of ground feldspar from 1939 to 1942, as reported by merchant grinders, are shown in the accompanying table. Shipments during 1942 to California, Illinois, and West Virginia increased considerably over 1941 but to New York only slightly. Other States for which comparisons are possible showed smaller totals than in 1941, although generally quantities compared favorably with those for prior years. In 1942 the largest consuming State was Illinois, with shipments amounting to 50,450 short tons or 15 percent of the total; it was followed by Ohio with 43,950 tons (13 percent), New Jersey with 43,029 tons (13 percent), Pennsylvania with 40,013 tons (12 percent), and Indiana with 38,998 tons (12 percent). Next in order were West Virginia (11 percent), New York (6 percent), and California (4 percent). Shipments to "Other destinations" comprised 4 percent of the total in 1942, including fair-size tonnages to Arkansas, Louisiana, Mississippi, and Texas and small amounts to some 15 or 20 other States.

Other destinations [3]	25,463	27,721	40,271	13,877
	256,769	285,713	354,417	327,786

[1] Data include 99 percent of total ground feldspar.
[2] Included under "Other destinations"; separate figure for State not available.
[3] Includes Arkansas, Colorado, District of Columbia, Hawaii, Kentucky, Louisiana, Maryland (1939–41), Massachusetts (1939–41), Michigan, Minnesota, Mississippi, Missouri, Oklahoma (1939–41), Puerto Rico, South Carolina, and Texas, and other States (shipments to which cannot be segregated); also small shipments to Canada, England, and Mexico.

NEPHELINE SYENITE

Production of nepheline syenite in 1942 continued active. In the first years it was used, practically all was employed in the manufacture of glass where its high alumina content proves economical and beneficial. In more recent years an increasing proportion of the output has gone into various types of ceramic bodies. The glass-trade material is of granular type, whereas nepheline for pottery use is finely ground. A residue or dust remaining from grinding finds an outlet partly in the enamel and colored-glass trades and partly as a substitute for pumice for grinding and polishing, as a cleanser, and in the heavy-clay industries.

Production in the last 2 or 3 years has come almost entirely from the Methuen Township region in Peterborough County, Ontario. Deposits of similar occurrence extend over into Hastings and Haliburton Counties. The Bancroft-Gooderham district northeast of the Methuen region in Hastings and Haliburton Counties has produced intermittently since 1937. A new Canadian source of nepheline syenite is the property of Port Coldwell Mines & Metals, Ltd., recently reported to be under development[2] at Port Coldwell, Ontario.

The larger part of the Canadian output is shipped into the United States for grinding and consumption, although some nepheline is ground before importation. After considerable increase in 1941 over 1939 and 1940, imports of crude nepheline syenite in 1942, although only slightly above 1941, reached the record figure of 35,990 short tons valued at $120,688. Comparable data are 35,799 tons valued at $112,101 in 1941 and 27,888 tons valued at $87,162 in 1940. Ground nepheline syenite imported into the United States totaled 4 short tons valued at $44 in 1942, which compares with 6 tons valued at $25 in 1940; in 1941, however, 1,359 short tons of ground nepheline valued at $13,695 were shipped into this country. All shipments of crude and ground nepheline originated in Canada.

Prices of nepheline syenite at the end of 1942, according to Canadian

Chemistry and Process Industries, were the same as at the beginning of the year: Grade A, 20-mesh, bulk, in carlots, $11.75 per ton f. o. b. Lakefield, Ontario; Grade A, 200-mesh, bulk, in carlots, $16.50 per ton f. o. b. Kingston, Ontario; and Grade B dust, bulk, in carlots, $10.00 per ton, f. o. b. Lakefield, Ontario.

Nepheline syenite prices were included under the Office of Price Administration General Maximum Price Regulation (G. M. P. R.) of April 28, 1942, and also under Maximum Price Regulation (M. P. R.) 327, issued February 16, 1943, and effective February 22, 1943. This latter regulation established as the maximum allowable prices those prevailing in March 1942.

The only known commercial production of nepheline syenite, other than from Canadian deposits, is that from apatite nephelite rock on the Kola Peninsula in northwestern U. S. S. R. Montana pegmatites, said to resemble in part the Kola Peninsula deposits, were described by Pecora.[3]

APLITE

Production of ground "aplite" by Dominion Minerals, Inc., with mill at Piney River, Va., continued at an active rate in 1942, surpassing slightly shipments reported for 1941. New uses, especially for the large quantities of fines produced as a byproduct of milling operations, are being investigated. Among possible new uses may be fillers of various types and a quite recent application—the extinguishing of incendiary magnesium bombs.

The new mill of the Carolina Mineral Co., Erwin, Tenn., subsidiary of the Consolidated Feldspar Corporation, began operations during 1942, grinding material similar to that processed by Dominion Minerals, Inc. The new plant also is located near Piney River, Va.

TECHNOLOGIC DEVELOPMENTS

Considerable data on the fluxing properties of feldspar and nepheline syenite were developed and published in a paper by Earhart.[4] In a study of the effect of fluxes containing mixtures of spodumene and feldspar on semivitreous and vitreous hotel-chinaware bodies, the most effective fluxes were found to be those consisting of 30 to 40 percent spodumene, 40 to 60 percent potash feldspar, and 10 to 20 percent soda feldspar.[5] Formulas for determining the relative amounts of microcline, albite, anorthite, kaolinite, muscovite, and free quartz in the feldspars were published by Koenig.[6] The extent and nature of feldspar-bearing sands in Illinois and the most economical methods of separating and preparing commercial grades of feldspar from them were investigated by the State Geological Survey during 1942.[7]

Feldspar has been found to be effective in extinguishing magnesium

incendiary bombs,[8] as a result of experiments by W. W. Rubey, geologist, and Michael Fleischer and J. J. Fahey, chemists, Federal Geological Survey. With a melting point of about 2100° F.—lower than that of sand—feldspar quickly forms a protective coating over the molten magnesium which cuts off the supply of air from the magnesium and actually stops it from burning and its flame from spreading. It is superior to mixtures containing salt, pitch, ashes, or fine powders, as it does not burn, give off smoke, blow out, or scatter appreciably from the intense heat of the incendiary material. Feldspar used for this purpose should be ground to pass a 10-mesh screen and be retained by a 200-mesh screen. Finer material tends to clog interstices and prevent the ready escape of gases, which otherwise would erupt with sufficient force to form miniature craters in the feldspar cover and destroy its effectiveness.

Costly equipment or a trained crew is not needed to apply the extinguisher. Feldspar also is relatively inexpensive. Indeed, the waste material produced in grinding commercial grades of spar could readily be screened to suitable size and marketed for this purpose at comparatively low cost, according to the Geological Survey.

In most of the Survey experiments, the rock used consisted largely of soda-lime feldspar. This rock, locally called "aplite," is quarried in Amherst and Nelson Counties, Va., where there is an abundant supply. Potash feldspar, either orthoclase or microcline, is equally effective. Rocks consisting largely of feldspar also give practically as good results as pure feldspar. In the East such materials as syenites, nepheline syenites, or screenings from granite quarrying might be used. Granite, monzonite, rhyolite, and latite are available and quarried for crushed stone in the Pacific Coast area. Screenings from these crushed rocks, although perhaps not as effective as feldspar, could be utilized as magnesium extinguishers.

The United States Department of the Interior, by arrangement with the inventors acting through the Department of Justice, already has taken steps to obtain Government-controlled patent protection for the invention and method of use. Under the patent,[9] commercial development of the material under free licenses will be encouraged by the Department. Consumer prices for material used in extinguishing incendiary magnesium to be sold under the above-noted patent, were established by the Office of Price Administration.[10] Up to February 1943, sales of extinguishers manufactured by license had been made in Baltimore and Philadelphia. Applications for licenses also had been received from potential manufacturers elsewhere in the East, on the West coast, and in the Gulf of Mexico area. Interest in the extinguisher has been shown by airfields and by factories using magnesium in their products.

OTHER DEVELOPMENTS

The property of the Seaboard Feldspar Corporation in Cheshire County, N. H., was acquired in July 1942 by the General Minerals Corporation, 52 William Street, New York City, and operation con-

tinued during the year. In August 1942, the F. E. Schundler Feldspar Co., Inc., Custer, S. Dak., discontinued business, and the company was dissolved. The Consolidated Feldspar Corporation, Trenton, N. J., also operating a mill at Keystone, S. Dak., acquired the mines and mill of the Schundler firm and operated the plant for the rest of the year. The Bureau of Mines has been informed that a feldspar mill is to be erected in the Llano area at Kingsland, Tex., to process a low-iron spar recently discovered in the Packsaddle Mountain district.

Brief descriptions of feldspar deposits are given and the relative importance of the New York feldspar industry is discussed by Otte.[11] The feldspar occurrences in the Llano County region in Texas were described by Chelf.[12] Two plants of the Consolidated Feldspar Corporation, whose main offices are in Trenton, N. J., were described in the trade press. Hubbell [13] presented a detailed account of the equipment, products, and methods of operation of the corporation plant at Erwin, Tenn., which processes feldspar from the Spruce Pine area of North Carolina; and Moore [14] described operation of the mines and mill near Bedford, Westchester County, N. Y.

IMPORTS [15]

Feldspar.—Crude feldspar imported into the United States in 1942 aggregated 9,525 long tons valued at $69,797—a decrease of 15 percent in tonnage and 5 percent in value compared with 11,253 tons valued at $73,236 imported in 1941; the average value per ton ($6.51 in 1941) increased 13 percent to $7.33 in 1942. All imports originated in Canada. In 1942, as in 1940 and 1941, there were no imports of ground feldspar.

Feldspar imported for consumption in the United States, 1938–42

Year	Crude		Ground		Year	Crude		Ground	
	Long tons	Value	Short tons	Value		Long tons	Value	Short tons	Value
1938	7,651	$56,126	----------	----------	1941	11,253	$73,236	----------	----------
1939	7,460	52,141	2	$54	1942	9,525	69,797	----------	----------
1940	12,522	80,274	----------	----------					

Cornwall stone.—Both "unmanufactured" and "crushed or ground" Cornwall stone from the United Kingdom (only source of supply for this material) were actively imported into the United States during 1941; in 1942, however, shipments virtually ceased. The average values (foreign market value) per long ton for unmanufactured material in 1940, 1941, and 1942 were, respectively, $9.20, $11.38, and $13.80 and for crushed or ground Cornwall stone, $12.10, $14.60, and $18.40.

SUMMARY

Sales of domestic asbestos in 1942—15,481 short tons—were 37 percent less than those in 1941. The decline was confined to the chrysotile variety, sales of which were smaller both in Vermont and Arizona. The value of total sales was 31 percent lower. Sales of the amphibole variety were slightly higher in both quantity and value than in 1941. Most of the United States production is of the shorter grades of chrysotile. During 1942 domestic production furnished less than 4 percent of domestic requirements.

As in the past, Canada supplied most of the United States needs of unmanufactured asbestos. Canadian chrysotile is of excellent quality and is suitable for most asbestos products, although a few specialties require asbestos from other sources. African chrysotile, which is imported in substantial quantities, is an important supplement to Canadian fibers of spinning grade. India and Soviet Russia are other sources of chrysotile for general use.

Asbestos combines noninflammability with a fibrous structure that makes it the unique source of unburnable fabrics. Because of this peculiar combination of properties it is an irreplaceable material for certain important military uses, although for some common uses substitution is possible. The most important application in the former category is for brake linings and clutch facings on automobile transport equipment. No satisfactory substitute has been found for these uses. As all types of automotive transport must have brakes and clutch facings, it is apparent that the military needs are extensive and of primary importance. Fortunately, any strong, flexible chrysotile of spinnable length is satisfactory for such use, and the extensive asbestos-producing industry of Canada can supply large quantities of satisfactory material. The demands for spinning fibers in this field are relieved to some extent by the substitution of molded for woven brake bands. The molded bands employ shorter grades of fiber, but they can be used only on certain types of brakes. Other important asbestos products are gaskets and packings around steam and com-

Digitized by Google

pressed-air machinery. These products are also of great military importance because they are used on warships, by the merchant marine, and in even larger quantities at power plants and innumerable munition factories.

Still another important field of usefulness for asbestos is heat insulation. Asbestos is a popular insulating medium; but other materials are substituted for it to some extent, and further substitution in the general insulation field is possible. There are, however, certain types of insulation for which special grades of asbestos are essential if weight is to be conserved and efficiency maintained.

The most widespread occurrences of asbestos in the United States are those of the amphibole type—anthophyllite and tremolite. Hundreds of deposits are known, but production never exceeds a few hundred tons a year because the uses are quite limited. Its resistance to acids renders tremolite useful for making chemical filters; the amphibole varieties are employed also in arc welding and in making insulation products, but the uses are so restricted and relatively so unimportant that they are not classed as critical.

Chrysotile asbestos is the principal variety of commerce and occupies an important place in the war program. The principal world production centers are Quebec (Canada), Rhodesia, Union of South Africa, Swaziland, and Soviet Russia. The Canadian mines and mills supply most of the United States needs, and the quality of the product is satisfactory for most of the important uses. African chrysotile is superior for electric-insulation products that must be low in iron and therefore is regarded as essential to the military program.

Amosite, a variety of asbestos mined only in Africa, consists of long, strong fibers that are superior for making lightweight insulation to be used around steam machinery on warships. Amosite also is preferred for making 85-percent magnesia pipe covering and a block insulation of similar type that contains no magnesia. This variety is therefore regarded as essential to the highest naval efficiency. In June 1942 the War Production Board promulgated Conservation Order M–79 restricting the use of amosite in 85-percent magnesia to certain military applications.

Crocidolite or blue asbestos is regarded as essential because it is superior to other varieties in making asbestos-cement pressure pipes, chemical filters, and acid-resistant packings. Long blue fiber is used also in making gas masks. Blue asbestos is mined chiefly in Africa, but small quantities are obtained in Australia.

Beginning January 1943, fiber obtainable from the two leading producing companies in Africa was purchased on United States Government account by the Metals Reserve Co. and allocated to the various asbestos-products manufacturers. This plan offered certain advantages in control of shipping routes, stimulation of production, and allocation according to the most urgent needs.

Throughout 1942 the Bureau of Mines conducted a monthly canvass for the War Production Board, covering receipts, stocks, and consumption. Stocks of critical grades of African fibers in the hands of consumers at the end of 1942 were adequate for 6 to 8 months' use at the average rate of consumption during the year.

Salient statistics on asbestos for 1941 and 1942 are summarized in the following table.

DOMESTIC INDUSTRY

REVIEW BY STATES

Arizona.—Production of asbestos in Arizona was less than half as great in 1942 as in 1941, according to reports of producers submitted to the Bureau of Mines. Sales, which were about two-thirds those in 1941, were made by the following companies: Arizona Chrysotile Asbestos Co., Arthur Enders, Guy G. Phillips, and Pine Top Asbestos Mines, all of Globe, Ariz.; E. E. Prochnow, Winslow, Ariz.; Fiber & Metal Products Co., Downey, Calif.; Gladding, McBean & Co., 2901 Los Feliz Boulevard, Los Angeles, Calif.; and Johns-Manville Products Corporation, 22 East Fortieth Street, New York, N. Y.

The Johns-Manville Products Corporation completed its new mill at Chrysotile, Ariz., but the output in 1942 was quite limited. When it attains normal operation the mill will afford a means of grading and classifying Arizona asbestos more accurately than has been possible in the past.

Digitized by Google

Pine Top Asbestos Mines began development of a property in the San Carlos Indian Reservation in May 1942, and shipments of fiber were made later in the year. Plans are under way for systematic development of the property and for erection of a mill.

California.—Kohler & Chase, 26 O'Farrell St., San Francisco, produced short-fiber chrysotile from its property near Monticello, Napa County. This was the only asbestos-mining activity noted in California during 1942.

Georgia.—The only activity reported from Georgia was that of the Powhatan Mining Co., which continued operation of its amphibole asbestos property near Dillard, Rabun County.

North Carolina.—Sales of North Carolina amphibole asbestos, only variety mined in the State, were 20 percent greater in 1942 than in 1941. W. T. Hippey and the Powhatan Mining Co. continued to operate their mines in the Micaville area of Yancey County. The Industrial Minerals Corporation (Asheville) began production from a new property near Newdale, Yancey County, early in 1942 and marketed substantial quantities before the end of the year. According to report, the asbestos-bearing rock mass is at least 200 feet wide and 400 feet long. It gives promise of production on a larger scale than is possible at most amphibole deposits.

Oregon.—A small quantity of tremolite asbestos was produced from a property owned by Mrs. Flora Winsenberg (Azalea, Oreg.) near Rogue River, Jackson County.

Vermont.—The Vermont Asbestos Mines Division of the Ruberoid Co. (500 Fifth Ave., New York, N. Y.), largest producer of asbestos in the United States, continued to operate its open-pit mine and well-equipped mill near Eden, Lamoille County. Shingle stock and molded brake-lining fiber are important products, but several shorter grades are produced in large quantities. The volume of output was somewhat lower than in 1941.

TRENDS IN CONSUMPTION

Trends in the asbestos-products industries during recent years are indicated in the following table.

Raw asbestos consumed in the United States and asbestos products manufactured in and exported from the United States, 1937–42

Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—		Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—	
		Manufactured [1]	Exported [2]			Manufactured [1]	Exported [2]
1937	316,263	$96,347,570	$3,047,078	1940	262,199	(4)	$3,473,248
1938	187,150	(4)	2,533,916	1941	[3] 438,741	(4)	4,835,194
1939	255,547	97,944,735	3,354,920	1942	434,121	(4)	5,114,496

[1] Figures of Bureau of the Census (collected biennially for odd years) include value of certain gaskets, packing, and similar products in which little asbestos was employed.

[3] Revised figures.
[4] Data not available.

Under normal conditions the consumption of asbestos is governed to quite an extent by the number of automobiles manufactured, be-

Digitized by Google

cause all kinds of automotive transport equipment require asbestos brake bands and clutch facings. During 1942 the manufacture of automobiles was virtually suspended and therefore ceased to be a market indicator. Activity in building construction also influences asbestos sales, because asbestos heat-insulation and fireproofing materials as well as asbestos-cement building materials (such as shingles, siding, and wallboard) are used extensively. Private building declined greatly in 1942, but military construction (including defense housing) was very active and was responsible for large sales of asbestos products. Industrial activity, which maintained a very high level, involved extensive power-plant construction. Large quantities of packings, gaskets, boiler lagging, and pipe covering were consumed in these plants and in multitudes of munition factories. Asbestos is an essential raw material for ship construction, and the rapid expansion of the Navy and Merchant Marine accounted for a large proportion of the sales of high-grade fibers during 1942. Figure 1 shows the relationship of asbestos consumption to building construction and industrial activity for a period of years. It is evident that asbestos consumption is related more closely to industrial activity than to building construction.

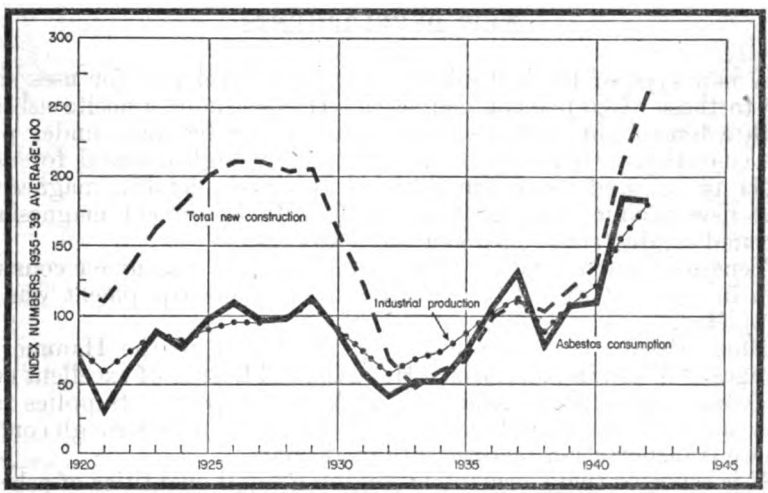

FIGURE 1.—Consumption of asbestos compared with total new construction and industrial production, 1920–42. Units are reduced to percentages of the 1935–39 average. Statistics on the value of construction from the Bureau of Foreign and Domestic Commerce and on industrial production from the Federal Reserve Board.

MARKET CONDITIONS

Over-all market demands for asbestos, which surpassed in 1941 all previous records, declined slightly in 1942. Needs in the automobile industry were confined largely to replacements, but loss of market in this field was compensated by the growing demands of the war program. Civilian uses of the more critical grades were restricted to insure adequate supplies for war needs. The demand for spinning fibers was very strong and threatened to outstrip the supply during the latter part of the year.

Digitized by Google

PRICES

Prices for asbestos are quoted upon a short-ton basis from Metal and Mineral Markets, published by the McGraw-Hill Publishing Co., Inc., New York City. Canadian prices are f. o. b. Quebec mines, tax and bags included; Vermont prices are f. o. b. mines, Hyde Park, Vt.

Prices of all Canadian fibers remained at the levels of 1941, as quoted in Minerals Yearbook for that year, until April 1942, when all grades except Crude No. 1 were advanced as follows and remained constant thereafter: Crude No. 1, $650–$750; Crude No. 2 and sundry crudes, $165–$385; spinning fibers, $124–$233; magnesia, and compressed sheet fibers, $124–$146.50; shingle stock, $62.50–$85; paper stock, $44–$49; cement stock, $28.50–$33; floats, $19.50–$21; and shorts, $14.50–$26.50. Canadian prices are in United States dollars.

African and Russian fibers were not quoted during 1942.

In April 1942 prices of all grades of Vermont fibers were advanced substantially from 1941 figures. Quotations from April to the end of the year were as follows: Shingle stock, $62.50–$65.50; paper stock, $44–$53; waste, $33; shorts, $14.50–$28.50; and floats, $19.50.

NEW DEVELOPMENTS

A new type of block insulation has been developed for uses similar to those of 85-percent magnesia. It consists of amosite asbestos with a binder but contains no magnesia—an advantage under present conditions, when there is an abnormally high demand for magnesia to be used in making refractories and metallic magnesium. The new product compares favorably with 85-percent magnesia in thermal conductivity, shrinkage, and strength.

Venezuela's new asbestos mill near Tinaquillo was under construction in 1942 but owing to difficulties in securing equipment was not completed.

Blue asbestos is now mined in a small way in the Hammersley Ranges of Western Australia. Hand-cobbed fiber is of excellent quality, commanding about $300 a ton at American ports. Supplies from this source are not great because the deposits are in very rough country where transportation facilities are inadequate.

It is reported that Germany is obtaining small quantities of asbestos in Norway. The small pre-war output of Finland, Italy, and Czechoslovakia would be entirely inadequate for German war needs. No data are available on the increased output from the small known sources of asbestos in Central Europe or the extent of reserve stocks held by Germany, and only meager information is at hand on substitute materials.

An asbestos-graphite lightweight molded product has been developed recently and sold under the trade name "seybolite." It is highly resistant to moisture, acids, alkalies, and fire. Suggested uses include molded seamless conduits, chemical containers, and fireproof panels for ships, trucks, and airplanes.

A new lightweight asbestos fabric sold under the trade name "asbeston" is taking the place of critical metals in aircraft fittings, such as carburetor-intake attachments, heater-hose nozzles, and defrosters.

FOREIGN TRADE [1]

The following table shows imports of unmanufactured asbestos into the United States in 1941 and 1942. The volume of imports in 1942 was virtually unchanged from 1941. Imports from Africa were only slightly lower than in 1941 even though ship sinkings caused several serious losses. As most of the African fibers are of strategic grades, it is highly desirable to maintain imports at undiminished levels. Canadian imports fell a little below those of 1941, but the value of imports was more than 3 million dollars higher, due chiefly to advance in prices; larger purchases of the better grades of fibers probably accounted for some of the increase.

Asbestos (unmanufactured) imported for consumption in the United States, 1941–42, by countries and classes

Country	Crude (including blue fiber)		Mill fibers		Short fibers [1]		Total

CANADA

Canadian mines and mills were operating virtually at capacity during 1942. Supplies of mill fibers were ample for United States requirements, but a possible shortage of No. 2 crude was threatened during the latter part of the year. It is claimed that the percentage of crude fibers recovered in the Quebec mines is declining, and the cause of the decline is attributed to the method of mining. Several of the larger mines now employ the block-caving method, which involves undermining great masses of asbestos-bearing rock and removing the broken stone from tunnels underneath the rock mass. The block of stone is shattered under the stress of forces set up as it settles unevenly; and as the fiber veins are planes of weakness, shatter cracks tend to follow the veins, breaking them up in such a manner that much of the fiber—formerly hand-cobbed as crudes—is mixed with the rock and recovered later as mill fiber. The United States is so dependent on Canada for its high-grade fibers that all such trends must be followed closely.

The following figures have been released by the Department of Mines, Province of Quebec, for strictly confidential use.

Sales of asbestos in Canada, 1941–42, by grades

	1941			1942		
	Short tons	Value		Short tons	Value	
		Total	Average per ton		Total	Average per ton
Grade:						
Crudes	2,845	$980,217	$344.54	2,890	$1,233,184	$426.71

Rock mined	7,712,367			8,233,516		
Rock milled	6,366,670			6,795,459		

AFRICA

Southern Rhodesia.—The Shabani mine has been an important producer for many years and is probably producing at near maximum capacity. Other smaller mines add to the supply. Because of war restrictions, no figures of output have been released since May 1940.

Union of South Africa.—The Union of South Africa is unique in that it produces five kinds of asbestos—chrysotile, crocidolite, amosite, anthophyllite, and tremolite. The last two varieties are produced in small amounts, for local use only. Some years ago there was a large production of chrysotile from the Amianthus and Munnik Myburgh mines in the Kaapsche Hoop district of eastern Transvaal. The mines are now virtually worked out, but the loss from these sources is more than compensated by production from the recently developed Havelock mine in Swaziland, which has an annual output exceeding 24,000 tons of high-grade fiber.

Although exports of amosite and blue asbestos were considerably higher in 1942 than in 1941, stocks at the mills were maintained at normal levels. Added equipment has increased mill capacity.

Digitized by Google

The best blue fiber (crocidolite) occurs in the Prieska and Kuruman districts of Cape Province, where the largest production is centered. A small output is obtained in the Pietersburg district of Transvaal. The workings are shallow, and the product is less desirable than the Cape blue.

The following table shows production during recent years. Production in 1942 exceeded all previous records.

Asbestos produced in the Union of South Africa, 1938–42, by sources

Year	Short tons				Total value [1]
	Transvaal	Cape Province	Natal	Total	
1938	16,505	6,484	[2] 187	[2] 23,176	£416,401

[4] January to September, inclusive.
[5] Includes 187 tons in 1938 and 79 tons in 1939 produced in Natal.
[6] Preliminary.

SOVIET RUSSIA

Nearly all the Russian asbestos produced originates in the Bajenova district of the Urals, where there are both mines and mills. No production statistics are available since 1938, when an output of 86,000 metric tons was reported. Under the third Five-Year-Plan, an expansion of production capacity to 220,000 metric tons a year was contemplated. Such an objective was expected to be attained in 1942. The bulk of the output would, as heretofore, be used in domestic asbestos-products plants. Among world producers the Soviet Union stands next to Canada on a tonnage basis, but, like Canada, a large share of the output consists of the shorter grades.

Digitized by Google

Canada's shorter grades find ready market in nearby United States, but in Soviet Russia the short fibers are consumed by large domestic asbestos-products manufacturing industries. The Russian industry probably has expanded greatly to provide brake bands and clutch facings for the Union's growing automotive transport system and to furnish gaskets, packings, and heat insulation for its numerous immense munition factories. Russian reserves are estimated at 18,000,000 tons of fiber.

OTHER COUNTRIES

In addition to the blue asbestos in Western Australia, mentioned under New Developments, other deposits have been discovered on the Australian Continent. A deposit of asbestos—probably chrysotile as it occurs in serpentine rock—has been found on the western shore of Macquarie Harbor about 18 miles from Strahan, Tasmania. The occurrences are conveniently situated for transport, being 4 miles from the Gordon River, which is navigable. Preliminary prospecting and testing have been conducted over an area of 300 acres.

Extensive occurrences of high-grade asbestos are reported on South Island, New Zealand, but are too inaccessible for development at present. Presumably, the necessary fiber will be obtained from Australian mines. One asbestos-cement-products plant is operated in New Zealand, and a second plant is contemplated because of a shortage of roofing and other building materials.

Considerable interest has centered recently on asbestos occurrences in Latin America. Reference has been made under New Developments to a large deposit of chrysotile in Venezuela. A deposit of blue asbestos has been known for many years in Bolivia and has been worked in a small way at intervals, but the quality is inferior to that of African blue. Small tonnages of asbestos are produced in Argentina for local use.

According to recent reports an asbestos-cement-products industry will soon be established in the State of Minas Gerais, Brazil. The factory presumably will be located at an asbestos mine that is about to be developed, but information regarding a more exact location is not yet available. A sample of the asbestos submitted to the Bureau of Mines appeared to consist of strong, flexible fibers of tremolite, but they were positively identified by the Geological Survey as anthophyllite. The occurrence of this variety of asbestos in fibers comparable in strength with chrysotile or high-grade tremolite is very unusual. Asbestos-cement board will be one of the chief products of the new factory; and, although anthophyllite found in the United States is unsuitable for such use, the Brazilian product seems to have suitable qualities. The entire output of the mine probably will be used in the local plant.

Samples of chrysotile of good strength and flexibility were received by the Bureau of Mines in 1942 from a deposit reported to be in the Department of Junin, Peru, on the eastern slope of the Andes.

During 1942 the Bureau of Mines received samples of fair-quality chrysotile asbestos from deposits in Mexico, somewhere in the vicinity of the Laredo-Mexico City highway. The asbestos-bearing rock is said to be an outcrop of serpentine 10 kilometers long and 1.5 kilometers wide, in which more than 20 fiber veins occur. Some of the samples

Digitized by Google

examined by the Bureau of Mines consisted of cross-fiber veins of spinning fiber comparable in quality with Canadian asbestos, except that they were stained and discolored. This condition probably was due to surface alteration.

Chrysotile asbestos was discovered in Turkey in 1934. According to Turkish authorities, the deposit is between Karakose and Kogizman in the vilayet of Agri. Because of remoteness and technical difficulties, it has not been developed. Short-fiber asbestos suitable only for asbestos-cement products and insulation is produced in small quantities in the Eskisehir region. It is reported that small shipments were made to Germany and Hungary in 1942.

A small output of asbestos was reported from the Macheria deposit, Algeria, in 1942. No information is available on the variety or quality of the fiber.

Cyprus normally produces several thousand tons of short-fiber chrysotile a year, and as there is virtually no local market the entire output is exported. Shipping conditions were quite difficult in the Mediterranean Sea during 1942, and presumably the Cyprus industry has been relatively inactive. As no new data have been obtained, the table that appeared in Minerals Yearbook, 1941, has not been repeated in this chapter.

SUMMARY

The war and other factors caused substantial declines in the use of barite in certain industries but fostered expansion in other ways, so that the net demand remained high. More crude barite was produced in 1942 (449,873 short tons) than during any previous year except 1941 (483,391 tons). The quantity of crude barite sold or used by producers in 1942—429,484 tons valued at $2,673,002—was exceeded only by 1941 sales—503,156 tons valued at $3,134,234.

The largest single loss in markets for ground barite was in rotary oil-well drilling muds, reflecting a general decline in well-drilling activity in the United States. Demand for drilling muds in Trinidad and Venezuela was active, but sufficient shipping space was not available to meet requirements. Consumption of barite for lithopone and blanc fixe manufacture also decreased, owing to the curtailed use of the finished products in paints and civilian white goods, such as linoleum, oilcloth, and rubber goods.

The quantity of crude barite consumed in making barium chemicals reached an all-time high in 1942. However, the tonnage of chemicals produced declined slightly owing to the reduced output of lithopone, which requires less barite per unit weight than other barium chemicals. Sales of barium carbonate, principally for use in case-hardening steel and in preventing efflorescence in structural brick, increased substantially, as did sales of barium nitrate for flares and barium peroxide for hydrogen peroxide manufacture.

Imports of crude barite in 1942 were 4,680 short tons from Canada and Cuba compared with 456 in 1941, all from Cuba. Imports of witherite (from Great Britain) were 3,066 tons in 1942 compared with 4,790 in 1941. Exports of barite from the United States are not reported separately.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

[1] F. o. b. mine shipping point.
[2] Declared value f. o. b. foreign market.
[3] Barite sold or used by producers plus imports.
[4] 1938–41: To avoid duplication, the barium chemicals reported here do not include the output of firms that make these chemicals from such products as barium chemicals and imported barite and witherite purchased in the open market. 1942: Includes barium chemicals made from barium chemicals and imported barite and witherite purchased in the open market. The data have been adjusted to remove duplication.

BARITE

CRUDE

PRODUCTION

Total mine output of crude barite in 1942—449,873 short tons—was greater than in any previous year except 1941, when a record quantity—483,391 tons—was mined. Excellent demand maintained mining activity at high levels in the Southern, Midwestern, and Western barite-mining districts throughout the year.

When imports of German barite began to decline in 1938, production in the Southern district (Alabama, Georgia, South Carolina, Tennessee, and Virginia) expanded to meet requirements on the East coast. These requirements totaled about 220,000 tons annually, including about 180,000 tons of domestic origin, chiefly from the Southern district, and about 40,000 tons of crude imported barite, mostly from Germany. The German barite found a ready market on the East coast despite an import duty of $4 a ton. In meeting wartime demands, production of crude barite in the Southern district in 1942 exceeded all previous years except 1941. In the Midwestern district

Digitized by Google

(Missouri and Arkansas) production increased slightly, as losses in well-drilling-mud markets were compensated by increased demands of lithopone and barium chemical plants in Illinois and Missouri. In the Western district barite output declined slightly, owing to decreased use of barite in California well drilling, but requirements for the manufacture of barium chemicals at Modesto, Calif., remained substantial. Barite was produced in Nevada and New Mexico; the output in the latter State was held in stock.

Crude barite sold or used by producers in the United States, 1941–42, by States

State	1941		1942	
	Short tons	Value	Short tons	Value
Georgia	104,446	$553,445	86,636	$483,261
Missouri	212,718	1,337,756	146,270	943,131
Tennessee	104,511	779,565	83,291	624,584

	503,156	3,134,234	429,484	2,673,002

[1] 1941: Arkansas, California, Colorado, Nevada, South Carolina, Texas, and Virginia; 1942: Alabama, Arkansas, California, Nevada, South Carolina, and Virginia.

Hubbell[2] prepared interesting articles on two of the largest producers of barite in the United States—L. A. Wood Co., Sweetwater, Tenn., and New Riverside Ochre Co., Cartersville, Ga. The L. A. Wood Co. operates seven open-pit mines in the Sweetwater district—the Stephens, Harmon, Garrison, Pond Creek, Fork Creek, Roy, and Calhoun. Each of the mines has its own washing plant, including log washers and jigs. The output of the mines is accumulated at a railroad yard for loading. The yard is equipped with a kiln for decrepitating some of the material to facilitate screening out iron oxide, thus yielding a purer product for glass use. The firm, under the name of the Barytes Mining Co. (Cartersville, Ga.), also mines barite from an open pit in north Georgia. Two grades of barite are produced at the Georgia mine—one about 96 percent barium sulfate, the other about 92 percent.

New Riverside Ochre Co. mines barite from five open pits in the Cartersville (Ga.) area. The crude material is dug with five caterpillar-mounted shovels and moved from the pits to the plant in trucks. Overburden ranges from a film to over 60 feet. Working benches are operated at about 15 feet. Approximately 8 tons of barite-bearing material are needed to produce 1 ton of washed barite. Treatment at the washing plant includes log washing, screening, crushing, jigging, and tabling. Three grades are produced: (1) A low-grade product containing about 92 percent barium sulfate and 5 percent iron oxide for use in oil-well drilling muds; (2) a 96-percent grade, maximum 1.0 percent iron oxide, for lithopone manufacture; and (3) glass grade, 98 percent barium sulfate, maximum 0.3 percent iron oxide. In making the glass grade, iron oxide is removed by magnetic separation.

Zapp[3] examined barite occurrences in the Llano (Tex.) area and

found that, although barite did not appear to occur commercially in the locality, core drilling might reveal larger deposits.

PRICES

The opening 1942 quotation for crude barite from Georgia was $8 a long ton, f. o. b. mine, rising to $9 in April 1942, according to E&MJ Metal and Mineral Markets. From 1935 to 1940 the price was $7 a long ton. Missouri crude barite, 93 percent $BaSO_4$, was quoted at $6 to $6.35 a long ton, f. o. b. mine, in January 1942, rising to $6.75 to $7.25 a long ton in April. Missouri crude, 95 percent $BaSO_4$, maximum 1 percent iron oxide, was quoted at $6.25 to $7.00 a long ton in January but rose to $7 to $7.50 in April.

The average value, f. o. b. mine shipping point, of crude barite for the entire United States, as shown by compilations from reports to the Bureau of Mines, was $6.22 in 1942 compared with $6.23 in 1941.

CONSUMPTION

Crude barite (domestic and imported) used in the manufacture of ground barite and barium chemicals in the United States, 1938–42, in short tons

WORLD PRODUCTION

Canada.—Barite output more than doubled in 1942 over 1941.[4] Of the total production, 16,667 short tons, Nova Scotia produced 14,849 and British Columbia 1,818. The Nova Scotia mine, at Walton, Hants County, is comparatively new, having begun shipments in 1941. It is operated by Canadian Industrial Minerals, Ltd., a subsidiary of Springer Sturgeon Gold Mines, Ltd. According to The Northern Miner,[5] the firm ships most of its output to Trinidad for oil-well drilling mud. About two-thirds of the Nova Scotia sales is ground barite and the remainder crude barite. The British Columbia deposit is 23 miles southeast of Golden; most of the output is shipped to a grinding plant at Montreal. The deposit has been known for a number of years, but until recent road construction was undertaken by the British Columbia Government it was inaccessible to trucks. Trenching indicates a large tonnage of a pure white barite, analyzing about 98 percent barium sulfate.

Cuba.—Shipments of barite from Cuba, going mainly to Trinidad and the United States, declined somewhat in 1942 compared with 1941,[6] probably owing to lack of shipping space. Cuban barite is produced in the Provinces of Oriente and Pinar del Rio. The latter area is the chief source, as the Oriente deposits are somewhat inaccessible. The Cuban output is ground at Regla near Habana.

Eire.—Barite is mined in western Ireland from a vertical fissure vein about 7 feet wide that cuts Carboniferous limestone, it is reported.[7] Benbulben Barytes, Ltd., operating the mine, ships crude, ground, and micronized barite, principally to Great Britain for use in lithopone manufacture and as a paint extender. The material analyzes about 96 to 98 percent barium sulfate, the impurities being chiefly silica.

Germany.—Before 1939 Germany was the chief producer of barite, supplying nearly half the world output. German production in 1937 was 452,388 and in 1938, 480,877 metric tons. Subsequent data are not available, but loss of export markets for crude and ground barite and barium chemicals has probably curtailed current output. Prussia is the chief producing State, followed by Baden. The barite occurs chiefly in veins and is recovered by underground mining.

Italy.—Annual production, which comes from about 40 deposits, is said to exceed 50,000 tons. The principal workings are near Trent, on the Island of Sardinia, in the Val D'Aosta, in Valassina, and in Tuscany.

United Kingdom.—Production of barite in the United Kingdom has increased greatly since 1939, owing mainly to cessation of imports from Germany. Large deposits of barite are available in Ayrshire, Devonshire, Shropshire, and Derbyshire, but it is said that production cannot meet demand.[8]

Much witherite is substituted for barite in England (see Witherite section of this chapter).

GROUND (AND CRUSHED)

SALES

All principal uses of ground (and crushed) barite sold or used by producers declined in 1942, and the total, though comparing favorably with pre-1940 output, was 24 percent less than the record 1941 sales. In its individual consumption outlets, demand for use in well drilling dropped 24 percent, in paint 40 percent, in glass 3 percent, and in rubber 35 percent.

	184,390	100	234,877	100	178,765	100

Virtually all barite is ground or crushed before use, but "ground (and crushed) barite" is generally held to mean barite ground for use other than in barium chemicals or lithopone, and such meaning is adhered to in this chapter. Nearly all ground barite is used for its physical rather than its chemical properties, except for the quantity consumed in glass batches.

As in years past, rotary oil-well drilling muds absorbed the greater part of the ground-barite output in 1942, although the number of wells drilled was considerably less than in 1941. The following table shows the relation between wells drilled and ground barite consumed in drilling muds.

Ground barite consumed in drilling wells in the United States, 1938–42

Year	Wells drilled [1]	Ground barite used (short tons)		Year	Wells drilled [1]	Ground barite used (short tons)	
		Total	Per well drilled			Total	Per well drilled
1938	26,712	126,697	4.74	1941	29,070	154,760	5.32
1939	25,987	125,560	4.83	1942	17,934	117,380	6.55
1940	28,124	138,055	4.91				

[1] Oil, gas, and dry wells drilled in United States, as recorded in chapters of this series on Crude Petroleum and Petroleum Products.

Barite has several functions in drilling muds, the principal one being to confine gas and oil to their respective formations during drilling. Barite drilling muds also seal the walls of the hole and lubricate the drilling mechanism.

Foreign demand for barite drilling muds has expanded considerably since 1938, particularly in Trinidad and Venezuela. American, Cuban, and Canadian producers competed in these markets in 1942. The Southern and Midwestern districts generally supply most of the ground barite exported from the United States for well drilling, shipping 10,000 to over 20,000 tons annually, depending on foreign demand, through Mobile, Ala., New Orleans, La., and other Gulf ports.

One of the newer uses for crushed barite is in glassmaking, where it acts as a flux in the glass batch, permitting lower furnace temperature or increased output at the usual temperature. Barium compounds, particularly precipitated barium carbonate, are used in optical, bottle, and flat glasses, not only as fluxes but to impart density and brilliance to the finished product. As barium glasses corrode

Digitized by Google

ordinary glass pots, special types of pots are generally required. According to a communication received by the Bureau of Mines from a large glass producer, the specifications of glass-grade barite are somewhat as follows: Barium sulfate, not less than 96 percent; moisture, not over 3 percent; iron oxide, not over 0.4 percent; titanium oxide, not over a trace; no particles coarser than 16-mesh; not over 3 percent plus 20-mesh; not over 40 percent minus 100-mesh; not less than 15 percent minus 100-mesh.

Ground barite has certain advantages as a paint extender. It has low oil absorption and fair sanding properties and contributes to a dense, nonporous film. Barite is added to inside paints to aid easy working with the brush; owing to the low oil absorption, considerable quantities can be incorporated without bodying. Its low tinting strength makes it a good base for colored as well as white pigments.

Ground barite is also used as a filler for paper, paper board, wallpaper, rubber goods, linoleum, and oilcloth. A recent novel use is in weighting concrete ballast for drydock caissons. Barium cements containing as much as 50 percent barium oxide have high specific gravity. This suggests their possible use, in conjunction with such heavy aggregates as barite, in making heavy concrete blocks to be substituted for pig iron in ships' ballast.

PRICES

The price quoted in Chemical Industries for ground barite, carlots, 350-pound barrels, works, was $27.65 a short ton in 1942, the same as in 1941.

FOREIGN TRADE

There were no imports of ground barite in 1941 and 1942. Imports for 1938–40 are shown in the salient statistics table of this chapter. Exports of ground barite are not reported separately.

WITHERITE

PRODUCTION

The Baroid Sales Division of the National Lead Co., which operates a mine near El Portal, Calif., is the only producer of witherite in the United States. Figures on output are not available for separate publication but are combined with those of barite.

Deposits of witherite in North America were reviewed in the chapter of this series in Minerals Yearbook, 1941.

Nearly the entire world production of witherite is centered in northern England. Sources, preparation, and uses of witherite have been reviewed by Muddiman [9] and Michell.[10] Jameson [11] reviewed methods of analyzing witherite.

In British paint formulas, ground witherite has been substituted for ground barite for mixing with ultramarine blue to make a green pigment, and it is claimed that such substitution improves the product.[12]

PRICES

According to Chemical Industries, the price of ground witherite in 1942 remained constant at $43 a short ton in carlots, bags, works, for the 90-percent grade, the same price as in 1941.

IMPORTS

Receipts of witherite were 3,066 short tons valued at $60,824 in 1942, all from Great Britain, compared with 4,790 tons valued at $107,238 in 1941. Exports of witherite, if any, are not reported separately.

Witherite, crude, unground, imported for consumption in the United States, 1938–42

BARIUM CHEMICALS

SALES

War conditions increased the demand for certain barium chemicals in 1942 but curtailed the production of others, particularly those whose principal uses were closely connected with civilian consumption.

All barium chemicals in the United States are derived from barite, except a small quantity obtained from witherite. Barite is crushed and roasted with coal, coke, or petroleum-coke breeze in a rotary kiln for

about 4 hours, yielding black ash, which contains about 80 percent barium sulfide. The black ash is leached with hot water to give barium sulfide liquor. There were 21 producers of black ash in 1942, compared with 18 in 1941. The Bureau of Mines does not report the output of black ash, as this is regarded as an intermediate barium chemical. Where possible only finished barium chemicals not used in the manufacture of other barium chemicals are reported.

Production of lithopone, long a major outlet for barite, declined in 1942 to 137,320 short tons, the lowest figure since 1938. There were nine producers in 1942, as in 1941. Paint remained the largest use of lithopone, but increasing military uses of paint did not compensate for losses in civilian paint markets caused by reduced construction of civilian dwellings and the shortage of painters for general maintenance work. Lithopone paint markets were also said to have been adversely affected by a growing use of titanium pigments in the white-pigment field. Shortages of linseed and other drying oils used with lithopone in the manufacture of linoleum and oilcloth held down production of these two commodities, which ordinarily consume 17,000 to 20,000 tons of lithopone annually. The declining production of rubber white goods has forced a corresponding decrease in the amount of lithopone needed for this purpose.

Lithopone[1] *sold or used by producers, 1940–42, by consuming industries*

Industry	1940		1941		1942

[1] Does not include cadmium lithopone.

Manufacturers of lithopone generally purchase washed and jigged barite analyzing about 96 percent barium sulfate, 1 to 2 percent Fe_2O_3, less than 1.75 percent silica, and no more than traces of zinc, lead, and fluorides. The barite is crushed and roasted with coal to form black ash as described above. The solution of barium sulfide obtained from black ash is reacted with a solution of zinc sulfate, whereby lithopone (barium sulfate intimately mixed with zinc sulfide) is precipitated; it is then dried, roasted, quenched in water, ground, bagged, and sold.

Lithopone has been suggested as a carrier pigment for luminous paints.[13]

The demand for blanc fixe declined owing to curtailment in use of white paint, rubber goods, linoleum, and oilcloth, its major outlets. Blanc fixe is made by reacting a solution of sodium sulfate with a solution of barium sulfide, precipitating barium sulfate (blanc fixe) and leaving a valuable byproduct—sodium sulfide—in solution. Blanc fixe is also a byproduct of the manufacture of hydrogen peroxide by the barium peroxide-sulfuric acid process. Five producers of

[13] Chemical and Engineering News, vol. 20, No. 8, April 25, 1942, p. 529.

Digitized by Google

blanc fixe reported to the Bureau of Mines in 1942 compared with six in 1941.

Barium carbonate production expanded to meet added demands in several fields. There were seven producers in 1942, five in 1941. This barium chemical is generally made by adding a solution of soda ash to one of barium sulfide, thereby precipitating insoluble barium carbonate, leaving byproduct sodium sulfide in solution. Probably the most important direct wartime use of barium carbonate is in salt baths for case-hardening bomb shells, tools, and other steel parts. Before the war witherite, being less costly, was employed for this purpose rather than precipitated barium carbonate; however, reduced imports of witherite have broadened, at least temporarily, the demand for the synthetic material. The action of barium carbonate as a carbon carrier in steel hardening is not precisely known, but when it is mixed with powdered coke and heated with iron parts at 1,700° F., the coke is gradually oxidized and the carbon content of the surface grains of the iron is increased, thus case-hardening the product. Other barium compounds, notably barium peroxide, are said to be capable of similar use. Barium carbonate is an intermediate in the manufacture of certain other barium chemicals, particularly barium peroxide and barium nitrate. In making the peroxide, barium carbonate is calcined with coke, yielding the oxide, which is then heated with air or oxygen under pressure, yielding a mixed barium peroxide-oxide. The percentage of peroxide obtained depends on the efficiency of the process used. Although most hydrogen peroxide is today made by electrolytic oxidation methods, substantial quantities of barium peroxide are still used to make hydrogen peroxide. There were three producers of barium peroxide in 1942, two in 1941. Barium carbonate can be used in glassmaking, as previously mentioned. The carbonate and other barium compounds are used in brickmaking to prevent formation of scum.

Barium nitrate is generally obtained by treating the carbonate with nitric acid. The nitrate is used in green signal flares and in explosives. In 1942, five firms reported production of barium nitrate compared with three in 1941.

Barium chloride, which may be crystallized from a solution of barium sulfide and calcium chloride, is used to purify salt brines for chlorine and sodium hydroxide manufacture, in making coatings for photographic paper, in the manufacture of extended titanium pigments, in color lakes, in finishing white leather, and in purifying beet-sugar juice. Three firms produced barium chloride in 1942, as in 1941.

Barium hydroxide was produced by four companies in 1942 (four in 1941), principally for use in beet-sugar purification and for refining animal and vegetable oils.

GENERAL CONDITIONS

Production and sales of domestic potassium salts continued to increase in 1942, with a record output of over a million and a quarter short tons of marketable potassium salts (1,267,455 short tons) containing 679,206 tons of equivalent K_2O. (See fig. 1.) The still

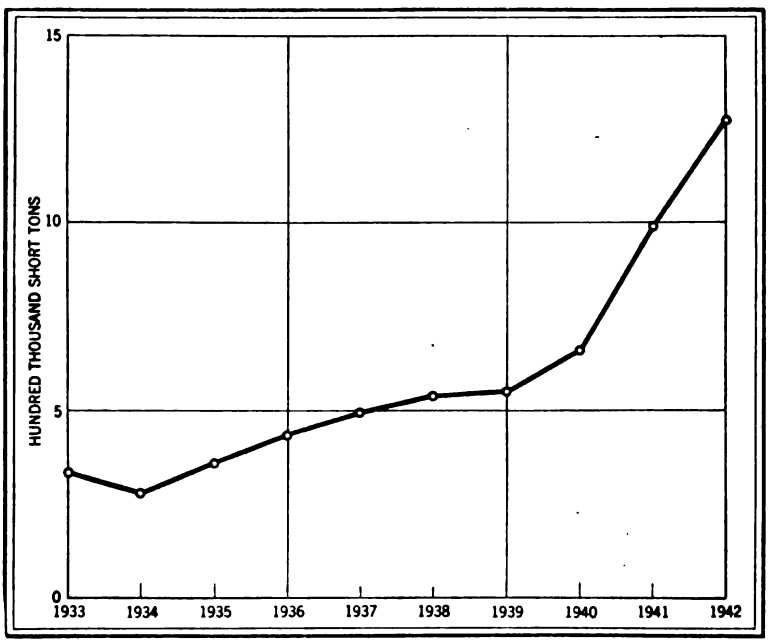

Figure 1.—Production of marketable potassium salts in the United States, 1933–42.

larger quantity sold (1,277,317 tons) carried 680,831 tons of equivalent potash (K_2O). Stocks in producers' hands at the close of the year continued to decline. Exports considerably exceeded imports. Domestic consumption was the highest on record—about 628,000 tons of K_2O. For the second year the United States has proved itself to be self-sufficient as to potash.

American potash producers are reported to have sold virtually their entire output to March 1943 early in 1942. Late in 1942,

Digitized by Google

according to trade journals, efforts of consumers, who had not adequately covered their requirements in the preceding spring, to obtain additional supplies created a tight market, which was alleviated irregularly by imports of muriate of potash from the U. S. S. R. on a lend-lease assignment to the Defense Supplies Corporation.

To assure equitable distribution of available domestic potash from producers to their immediate customers, largely the fertilizer companies, the War Production Board, on February 27, 1943, placed the distribution of domestic potash salts (muriate of potash, sulfate of potash, sulfate of potash-magnesia, and run-of-mine potash) under allocation control (General Preference Order M-291). This order was based upon the claim that the requirements for the defense of the United States had created a shortage in the supply of potash for defense, for private account, and for export. The order, effective April 1, 1943, covers three allocation periods: (1) April and May 1943, (2) the following 10 months, and (3) April and May 1944.

German control of a considerable part of the domestic potash production was exposed late in 1942.

General discussions of the domestic potash industry by Turrentine [1] and Kieffer [2] appeared in 1942. In 1943, a new book by Turrentine [3] described the development of the American potash industry since 1926 and supplemented his earlier book.[4] Domestic reserves of potash were described by Mansfield.[5]

PRODUCTION AND SALES

Domestic production of marketable potassium salts has increased each year since 1934, recent annual increments being much larger than those in the earlier years (see figure 1); in 1941 a 50-percent increase is shown over 1940, and in 1942 a 28-percent increase over 1941. Production in 1942 was 1,267,455 short tons, with an average K_2O content of 55.59 percent, compared with 53.21 percent K_2O reported for 1941. Production of equivalent potash (K_2O) in 1942 exceeded that of 1941 by 154,331 tons. Sales of potassium salts were over a million and a quarter tons in 1942 and contained 680,831 tons of equivalent potash (K_2O)—also a 28-percent increase over 1941. Sales exceeded production in 1942, and producers' stocks were drawn upon to meet the demand. The average value per ton of sales increased to $33.73 in 1942 from $32.69 in 1941. Production of 50 percent muriate was only a little larger than in 1941, but there was a 45-percent increase in the quantity of sulfate of potash and sulfate of potash-magnesia produced, as shown in the accompanying table of production by grades.

Potassium salts produced in the United States, 1941–42, by grades, in short tons

	1941	1942
Muriate of potash: 60 percent K_2O minimum	663,608	878,997
50 percent K_2O minimum	85,398	85,680
Manure salts, run-of-mine	154,979	183,404
Sulfate of potash and sulfate of potash-magnesia	82,473	119,374
	986,458	1,267,455

The potash industry of the United States is overwhelmingly a western one, more than 99½ percent of the 1942 output in terms of K_2O having come from California, New Mexico, and Utah. Nearly 81 percent of the equivalent potash (K_2O) production came from the deeply buried Permian saline sedimentary deposits of New Mexico and 19 percent from the saline lake brines of California and Utah, whereas less than 0.5 percent was recovered as a byproduct of manufacturing processes (cement and distillery operations in Maryland). The potash salts sold in 1942 were largely refined or processed products.

The potash-producing companies in the United States in 1942 were: The American Potash & Chemical Corporation, 122 East 42d Street, New York City (plant at Trona, on Searles Lake, Calif.); United States Potash Co., Inc., 30 Rockefeller Plaza, New York City (mine and plant near Carlsbad, N. Mex.); Potash Company of America, Carlsbad, N. Mex. (mine and plant near Carlsbad, N. Mex.); International Minerals & Chemical Corporation, 20 North Wacker Drive, Chicago, Ill. (mine and plant near Carlsbad, N. Mex.); Bonneville, Ltd., 540 West Seventh South, Salt Lake City, Utah (plant near Wendover, Utah); North American Cement Corporation, 41 East 42d Street, New York City (plant at Security, Md.); and U. S. Industrial Chemicals, Inc., 60 East 42d Street, New York City (plant at Baltimore, Md.).

PRICES

The General Maximum Price Regulation (Federal Register, April 30, 1942, pp. 3153–3158), issued April 28, 1942, under authority vested in the Price Administrator by the Emergency Price Control Act of 1942 and effective May 11, 1942, fixed potash prices at their March 1942 maximum.

Price lists for the 1942–43 fertilizer season were released by the major potash companies on dates ranging from May 29 to June 15, 1942. Most of the new schedules applied to the 12 months from June 1, 1942, to May 31, 1943. The Potash Company of America, however, released a schedule for the 10 months June 1, 1942, to March 31, 1943. The following base prices were reported by various producing companies.

Muriate of potash (62 to 63 percent), 62 percent K_2O minimum.	53½ cents per unit K_2O.
Muriate of potash, 60 percent minimum	53½ cents per unit K_2O.
Muriate of potash, granular (50 to 52 percent), 50 percent minimum.	56 cents per unit K_2O.
Manure salts:	
22 percent K_2O minimum	20 cents per unit K_2O.
25 percent K_2O minimum	21 cents per unit K_2O.
Sulfate of potash, 90 to 95 percent K_2SO_4—basis 90 percent K_2SO_4.	$36.25 per short ton.
Sulfate of potash-magnesia, 40 percent K_2SO_4 minimum, 18.50 percent MgO.	$26.00 per short ton.

Basing points for the New Mexico companies for muriate of potash were designated to be ex-vessel Atlantic and Gulf ports within the United States, and for the American Potash & Chemical Corporation ex-vessel principal continental United States ports. Prices for manure salts, where stated, were based upon Carlsbad, N. Mex., only. Sulfate of potash and sulfate of potash-magnesia prices quoted by the International Minerals & Chemical Corporation were ex-vessel Atlantic and Gulf ports within the United States. At buyers' option, muriate of potash could be purchased f. o. b. Carlsbad, N. Mex., at 11.2 cents per unit K_2O below ex-vessel price, and f. o. b. Trona, Calif., for 8 cents per unit K_2O below net ex-vessel price at Pacific coast ports.

Seasonal discounts offered by the Potash Company of America, the American Potash & Chemical Corporation, and the International Minerals & Chemical Corporation were 8 percent on orders accepted through June 30, 1942, for delivery in equal monthly installments from June 1, 1942, through March 1943, and 4 percent additional upon

Digitized by Google

completion of contracted deliveries; no discounts were allowed on orders placed after June 30, 1942. The United States Potash Co. allowed 8 percent discount from ex-vessel prices on orders placed for June delivery and on those placed before July 1, 1942, for equal monthly tonnage deliveries from June 1, 1942, to March 31, 1943, and 4 percent additional credit upon completion of contracted deliveries; on orders placed after June 30, 1942, but before October 1, 1942, for equal monthly tonnage deliveries from October 1, 1942, to March 31, 1943, it allowed 4 percent from ex-vessel prices and 2 percent additional credit upon completion of delivery of the contracted tonnage; no discounts were allowed on orders placed after September 30, 1942.

A 6-percent increase in freight rates went into effect in March 1942. The Office of Price Administration requested potash producers to absorb that part of the increase necessary to maintain ex-vessel prices at the established level. Later, a 3-percent tax on the transportation of property was imposed by section 620 of the Revenue Act of 1942, and the potash companies were also required to absorb this increase in a similar manner. In both instances, however, the buyer was required to pay the increased charges on potash sold at f. o. b. Carlsbad prices.

In February 1942, the Office of Price Administration issued a temporary order freezing retail prices of certain potash salts at levels prevailing from February 16 to February 20, 1942. These temporary price maximums were made permanent by Maximum Price Regulation 135—Mixed Fertilizers, Superphosphate, and Potash (Federal Register, April 30, 1942, pp. 3187–3189), issued and effective April 28, 1942. The prices of muriate of potash, sulfate of potash, manure salts, or any other substance containing K_2O when marketed or sold to consumers for use in growing crops and plants, and not for resale, were fixed at the above-mentioned February 1942 prices.

CONSUMPTION

In 1942 the United States and its possessions consumed potash salts containing approximately 628,000 short tons of K_2O, which were largely, though not entirely, of domestic origin. The following table, in which information from various sources has been combined, indicates a domestic consumption of 627,294 short tons.

Apparent consumption, calculated by subtracting exports (57,141 tons) from the sum of imports (4,359 tons) and producers' sales (680,831 tons), was 628,049 tons of K_2O in 1942. The difference in consumption figures obtained by these two methods is almost negligible.

Apparent domestic consumption of potassium salts, in terms of equivalent potash (K_2O), and its relationship to sales of domestic producers for a period of years are shown in figure 2.

A break-down of domestic deliveries of American potash by the major domestic producers according to use, as shown in the accompanying table, indicates that 90 percent in 1942 went to the fertilizer industry and 10 percent for chemicals. The picture is not quite complete, however, because no comparable break-down is available for imports or for sales of the minor domestic producers.

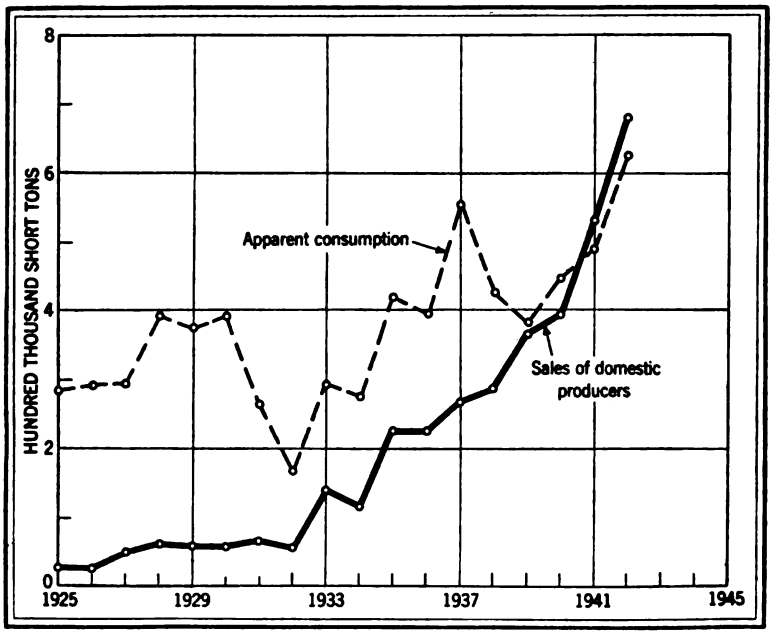

FIGURE 2.—Comparison of apparent domestic consumption of potash (K_2O) and sales of domestic producers of potash in the United States, 1925–42.

Sales of primary potash in the United States for consumption and export, 1940–42, in short tons of K_2O

	1940	1941	1942
Deliveries of potash of domestic origin by major companies, as from reports of American Potash Institute—			
In United States and possessions:			
Agricultural	321,414	435,940	558,356
Chemical	37,815	51,531	63,844
For export	23,707	24,807	37,955
	382,936	512,278	660,155
Imports for consumption plus sales of minor domestic producers	129,276	35,126	24,280
	512,212	547,404	684,435
Total exports	62,836	56,873	57,141
Actual sales for consumption in the United States	449,376	490,531	627,294

REVIEW BY STATES

California.—In 1942 the American Potash & Chemical Corporation (122 East 42d Street, New York City), only producer of potash in California, used the highly complex brine of Searles Lake, in the southeastern part of the State, as its raw material and produced both agricultural and chemical grades of potassium chloride, as well as potassium sulfate and potassium bromide, in its plant at Trona. Its total output of marketable potash salts was greater in 1942 than in 1941, when a long strike seriously affected production. Recent technical developments at the Trona plant are described by Robertson.[6]

German ownership of most of the capital stock and control of this company was disclosed by the Alien Property Custodian when he

announced, on October 20, 1942, the vesting in him of 90.79 percent of the capital stock of the company owned by German nationals. The property vested consisted principally of 474,726 shares, registered in the names of Consolidated Gold Fields of South Africa, Ltd., Gold Fields American Development Co., Ltd., New Consolidated Gold Fields, Ltd., and Administratickantoor Diligentia, all of which are beneficially owned by Wintershall A. G., Germany (dominant factor in the German potash industry) and Salzdetfurth A. G., Germany (second-largest potash company in Germany).

Maryland.—In Maryland, two companies have for several years produced a few thousand tons of byproduct potash annually for agricultural use. One of these, the North American Cement Corporation (41 East 42d Street, New York City), recovered a few thousand tons of impure sulfate of potash from cement-kiln flue dust in 1942 at its Security plant near Hagerstown, Md. U. S. Industrial Chemicals, Inc. (60 East 42d Street, New York City), continued to manufacture a byproduct potash-bearing material by incinerating waste residue from distillation of industrial alcohol from fermented molasses at its Fairfield plant, Baltimore. Blackstrap molasses has been used as raw material for several years but is no longer available; therefore, it has become necessary to use grain as a substitute source of alcohol. All grain residues will be recovered as distillers' dried grains and sold as such; consequently, no potash will be recovered.

New Mexico.—Mine production of the Carlsbad potash district has been climbing steadily. In 1940 it passed 1,200,000 short tons of ore, in 1941 it reached 2,270,000 tons, and in 1942 the three companies operating in the area mined 3,035,549 tons of sylvinite and langbeinite with an average equivalent K_2O content of 21.52 percent. All the companies mined sylvite (potassium chloride), and one—the International Minerals & Chemical Corporation— also mined langbeinite (a potassium-magnesium sulfate). The greater part of the production was sylvite, most of which was processed to yield 60 percent or higher-grade K_2O muriate. Potassium sulfate and potassium-magnesium sulfate were produced from langbeinite by the International Minerals & Chemical Corporation in the refinery at its mine near Carlsbad. Potassium sulfate also was produced by the Potash Company of America at plants in Oklahoma and Texas; this company also produced potassium hydroxide and potassium chlorate from sylvite at a plant at its mine near Carlsbad.

The Union Potash & Chemical Co., the most recent company to undertake potash mining in the Carlsbad area, merged with its parent company, the International Minerals & Chemical Corporation (formerly the International Agricultural Corporation), March 31, 1942. On October 31, 1941, a contract was completed with the Defense Plant Corporation whereby magnesium chloride cell feed would be produced from a waste potassium-magnesium-bearing brine, containing about 16 percent magnesium chloride, by a process developed by the International Minerals & Chemical Corporation. The magnesium chloride will be obtained by evaporation and selective crystallization, and the dried product will be shipped to a magnesium-metal plant at Austin, Tex., operated by the International concern. The potash-bearing solution remaining after removal of the magnesium chloride will be returned to the potash refinery, and the potassium salts previously wasted will be recovered. The magnesium chloride plant was under construction in 1942.

At the Potash Company of America plant an additional 2,400-horsepower Diesel engine was recently installed. Late in 1942 a 5-year contract was reported to have been concluded between the company and the City of Carlsbad, whereby the city would drill a well and supply water to a point near the Bataan Bridge over Pecos River. The company will pump the water to its mine for domestic and industrial uses formerly supplied by tank haulage.

One effect of the war is the loss to the company of cocoanut-oil soap, its principal flotation agent and previously imported, but satisfactory substitutes are said to have been developed. The company electrolytic plant was inactive for part of the year.

Utah.—In Utah three types of potash occurrences are being exploited—potassium-bearing brines, hydrothermal deposits of the potassium sulfate alunite, and bedded deposits of the potassium chlorides carnallite and sylvite. Only the first type is in commercial production, but the alunite deposits are being developed intensively, and the bedded chloride deposits are being tested.

Bonneville, Ltd. (540 West Seventh South, Salt Lake City), only potash producer in Utah in 1942, is obtaining potassium chloride from the potassium-bearing brine that saturates the thin, crystalline salt mass of Salduro Marsh, near the western edge of former Lake Bonneville in the Great Salt Lake Desert in northwestern Utah. The company output has increased each year since it began operating in 1938. Production was nearly 25 percent greater in 1942 than in 1941.

Interest in the alunite (a hydrous basic potassium aluminum sulfate) deposits of the Marysvale district, Piute County, has revived, particularly with regard to the aluminum content rather than the potassium content, which was considered more important during the First World War. Both vein and replacement alunite deposits occur. The vein deposits lie in Alunite Ridge between the forks of Cottonwood Creek. The replacement deposits are more numerous and are distributed much more widely. Total reserves of both types exceed 11 million tons of pure alunite, of which the vein deposits account for only 1,336,600 tons.[7] Mining operations in the Marysvale district in 1942 were concentrated at the White Horse mine (a replacement-type deposit) northeast of Marysvale, where an open-pit mine is being developed by Kalunite, Inc., Marysvale. Operations in 1942 comprised development work, preparation of the mine and crushing plant for production, road construction, completion of a bridge over Sevier River, and erection of buildings at the mine. The alunite ore will be sent to Salt Lake City for processing. None was treated in 1942, except in the laboratory. A plant to obtain alumina and potassium sulfate from alunite was being erected in 1942 in Salt Lake City. The Kalunite process to be used in this plant consists in (1) dehydrating the alunite, driving off the water of crystallization and then dissolving the product in dilute cyclic sulfuric acid and potassium sulfate solutions to form potash alum; (2) autoclaving the potash alum to a hydrous basic potassium aluminum sulfate; (3) calcining this sulfate to drive off sulfur oxides, thereby producing a mechanical mixture of alumina and potassium sulfate; and (4) leaching this soluble potassium sulfate from the insoluble alumina.

The Bureau of Mines carried out exploratory work (diamond drilling, trenching, test pitting, and sampling) on alunite deposits in the

[7] Thoenen, J. R., Alunite Resources of the United States: Bureau of Mines Rept. of Investigations 3561, 1941, 48 pp.

Digitized by Google

vicinity of Marysvale in 1942 and early in 1943 but temporarily suspended it February 25, 1943. The work, which was done on the Mineral Products, Yellow Jacket, Close In, White Horse, and Winkleman claims, indicated a large tonnage of alunite.

A study of the beneficiation of the replacement (disseminated) alunites from this region is included in a report by Gabriel and Dasher.[8]

In the Grand County potash field of eastern Utah in 1942 a well—known as Defense Plant Corporation-Utah Magnesium Corporation Reeder No. 1—was core-drilled by the Bureau of Mines with the cooperation of the Geological Survey, as agents for the financing Defense Plant Corporation, in the SE¼SW¼SE¼ sec. 4, T. 22 S., R. 19 E., about 7½ miles west-southwest of Thompson on the Denver & Rio Grande Railroad and about 1½ miles south of Crescent Junction. Material was moved on location May 1, 1942, and the well was spudded in on May 6 and completed August 3, 1942, at 4,207 feet.

The well is within the narrow, complexly strike-faulted zone along the crest of the long northwest-trending Salt Valley anticline, here plunging northwestward under Cretaceous cover. It started[9] in the Cretaceous Mancos shale and bottomed in the Paradox formation of the Pennsylvanian (Carboniferous). The well shows an abnormal geologic section, possibly due to an upthrust of the plastic salt-bearing Paradox formation into the fault zone. About 3,000 feet of sediments of Jurassic, Triassic, Permian, and Pennsylvanian age, normally expected to be present in this well, are missing. The Paradox formation extended from 2,091 feet to the bottom of the well. The section between 3,318 and 3,588 feet contained 91.6 feet of carnallite with an average assay of 39.5 percent carnallite. Individual carnallite beds were 1 foot to 13.5 feet thick and assayed 10 to 80 percent carnallite. There were two sylvite sections, the first extending from 3,419 to 3,518 feet, with 42 feet of sylvite averaging 24 percent sylvite, and the second from 4,152 to 4,157.5 feet and containing 5.5 feet of sylvite with an average of 41.3 percent of the mineral.

The normal thickess of neither the salt series nor the potash beds in this region is known. The salt core shows folding, flowage, and widely varying abnormal dips of the salt, as would be expected in squeezed and upthrust plastic salt beds. The wells of the district give no definite proof of the thickness or potassium content of the undisturbed saline beds of the region and little information as to their extent and distribution within the fault zone.

Late in 1942 the Potash Company of America (Carlsbad, N. Mex.) entered into a prospecting agreement with the Utah Magnesium Corporation, whereby the former is to drill a number of deep wells and to prospect the holdings of the latter company near Crescent Junction on which the above Defense Plant Corporation well was drilled.

FOREIGN TRADE[10]

The latest published information regarding United States exports and imports of potash salts in 1941 (chapter of Minerals Yearbook, 1941) covered only the period from January to September. In this chapter, figures for the full year 1941 as well as for the year 1942 are given.

Imports.—The United States, formerly a large potash-importing nation, now imports only a few thousand tons of potash salts annually under World War conditions. In 1941—the first year in which domestic production of potash exceeded national demand—imports had fallen to 62,255 short tons. In 1942 they dropped to 21,328 tons.

Late in February 1943 the Alien Property Custodian announced the vesting in him (Vesting Order 929, February 22, 1943) of all outstanding capital stock of the German-owned Pioneer Potash Co. This company had been incorporated in the United States to import and sell potash of German origin following the dissolution and liquidation of the N. V. Potash Export My., Inc., at the outbreak of war between France and Germany. The stock of the Pioneer Potash Co. was registered in the name of and was owned by N. V. tot Financiering van Industrieele Ondernemeingen Finindo, a corporation organized under the laws of the Netherlands, all of whose issued and outstanding capital stock is owned by Verrekeningskantoor ("Leata"), a Netherlands corporation of Amsterdam, Holland. All the issued and outstanding capital stock of this company is owned by the Deutsches Kalisyndicat G. b. m. H. (German potash trust).

Details as to the quantity, average grade, and declared value of the various potash salts imported into the United States in 1941 and 1942, and the approximate K_2O equivalent of the imports, are shown in the following tables.

Potash materials imported for consumption in the United States, 1941–42

Material	Approximate equivalent as potash (K_2O) (percent)	1941				1942

[3] United Kingdom of Great Britain and Northern Ireland.

Exports.—Substantial quantities of potash-bearing materials were exported from the United States even in former years when this country was a large importer of potash. Japan was the principal buyer in 1939 but was exceeded by Canada in 1940 and 1941. In 1942, 81 percent of the total exports of potash-bearing materials went to Canada.

Reinstated in this chapter is a table of exports by countries, omitted from the 1941 chapter for reasons of censorship.

Details regarding the exports of certain potassium-bearing fertilizer materials, by countries and by four subclasses, became available in the latter half of 1941. Such figures for 1942 are shown in a succeeding table.

WORLD PRODUCTION

Little information is available regarding the production of potash in foreign countries during recent years—for 1942, only figures for the United States, and for 1941, only those for the United States and Palestine. Since publication of the world-production table in Minerals Yearbook, 1941, a few additional figures for earlier years have become available; they are shown in the accompanying table.

Four nations dominate the world potash industry—Germany, United States, Soviet Russia, and Spain. Germany, now as heretofore, the dominant producer of western Europe as well as of the world, has bettered its position by the acquisition of the French and Polish potash industries and now holds all the important potash deposits of the western part of Europe except those of Spain. Soviet Russia, with its large reserves in the Solikamsk region, controls the potash industry of eastern Europe. In the Western Hemisphere the United States is by far the largest and almost the only potash producer. Its annual production, in terms of equivalent potash (K_2O), in 1942 exceeded the latest known K_2O output (1938) of France, at that time probably the second-largest producer in the world. The United States probably was the second-largest world producer in 1942; however, the relative position of the U. S. S. R. cannot be determined as statistics of its production are not available.

Total consumption of block and sheet mica	1467	World production	1474
Mica splittings	1468		

SUMMARY

Production of all kinds of mica except splittings increased in 1942. Although the over-all increase of sheet and punch (4 percent over 1941) was not as great as expected in view of the intense stimulation exercised to supply growing war needs, the quantity of the better grades increased substantially.

In June 1942, the Colonial Mica Corporation, a nonprofit organization, was designated by the Metals Reserve Co. as its agent to purchase strategic mica for the war industries, and in December 1942 this corporation was designated as the sole buyer of domestic strategic mica.

Splittings, which are used in a great variety of built-up mica products, are imported chiefly from India, although small quantities have been split mechanically in the United States, and an increasing quantity has been imported from Mexico. The Mexican splittings consist chiefly of Indian block mica re-exported to Mexico, where cheap labor is available for the manufacturing process.

The accompanying table of salient statistics gives the outstanding features of the mica industry during the past 5 years.

Approximately 65 percent of the total quantity of good-stained and better grades, sizes 5, 5½, and 6, are used for military radio condensers and magnetos, and up to the present time it has not been shown that lower than good-stained can be used in these products.

Stocks of good-stained and better mica on hand December 31, 1942, were sufficient for 8¼ months at the average rate of consumption during 1942. A break-down by sizes and qualities, however, shows that although the supply of grades poorer than good-stained is ample, the supply of good-stained and better grade of sizes 5, 5½, and 6 is not keeping pace with consumption. However, in the event of a critical situation it would be possible, though uneconomical, to use the larger sizes instead of the smaller to relieve the shortage.

Value	$664,419	$1,059,310	$2,484,128	$4,415,031	$9,044,875
Exports (all classes of mica):					
Short tons	1,772	1,827	903	1,163	1,001
Value	$183,889	$226,364	$191,550	$280,810	$303,526

[1] Includes mica recovered from kaolin and mica schists, as follows: 1938, 6,550 tons, $86,602; 1939, 10,011 tons, $108,899; 1940, 9,674 tons, $138,148; 1941, 15,583 tons, $185,486; 1942, 20,481 tons, $315,807.
[2] Exclusive of a nominal quantity of splittings produced in the United States and South America.

DOMESTIC PRODUCTION

Sheet mica.—Production in the United States increased to 2,761,844 pounds in 1942, valued at $725,030, compared with 2,666,453 pounds, valued at $566,858 in 1941. Eighty-eight percent of this, or 2,425,645 pounds, valued at $282,900, consisted of punch mica.

North Carolina, the largest producer in the United States, supplied 60 percent of the total punch and 61 percent of the larger sheet in 1942, compared with 61 and 54 percent, respectively, in 1941; and although this represents an advance in production, it failed to meet expectations.

South Dakota, which produced a large quantity of sheet and punch mica in 1941, increased its output in 1942 and became the second-largest producing State with an output of 399,224 pounds, valued at $75,687. Production in both Connecticut and New Hampshire declined in 1942.

The change in preparation from half-trim to three-quarter or full-trim of a large part of the mica produced had an important bearing on the increase in output. Because of better preparation, the yield per pound to the consumer was higher in 1942 than in any previous year. The increase in amount of usable mica per pound received was large enough so that although the quantity produced in New Hamp-

Digitized by Google

shire and Connecticut decreased, the value of the material was greater than in any previous year.

[1] Includes small quantities of splittings in certain years.
[2] 1941: Alabama, Arizona, California, Colorado, Georgia, Maine, New Mexico, New York, Pennsylvania, South Carolina, Vermont, Virginia, and Wyoming. 1942: Alabama, California, Colorado, Georgia, Idaho, Maine, Massachusetts, New Mexico, South Carolina, Texas, Vermont, and Virginia.

Scrap mica.—Production of scrap mica increased to 43,262 short tons valued at $671,165, compared with 32,500 tons valued at $442,789 in 1941. Besides mine scrap, this tonnage included mica recovered from washing kaolin or kyanite or by milling schist, which amounted to 20,481 short tons valued at $315,807, compared with 15,583 tons valued at $185,486 in 1941.

Ground mica.—Production of ground mica in 1942 reached 46,979 short tons valued at $1,653,358, compared with 43,419 tons valued at $1,532,351 in 1941.

Production of wet-ground mica decreased. Most of this is used in war materials, such as paints, protective coatings on tents and tarpaulins, plastics, and welding rods.

Dry-ground mica, which constitutes about 77 percent of all ground mica, is used chiefly in the roofing trade as a backing for rolled asphalt roofing and shingles to prevent sticking and, often, as a decorative surfacing for these materials. A small proportion of the finely ground material may be incorporated into the body of the roofing itself. Ground phlogopite mica is used as an ingredient in certain types of molded electrical insulation, in which it is bonded with natural or synthetic resins, gums, asphalts, rubber, silicate cements, or lead borate.

TOTAL CONSUMPTION OF BLOCK AND SHEET MICA

Government stimulation of domestic production and imports began to function efficiently in 1942. Monthly statistics of consumption and stocks of specific grades of block mica were first collected by the Bureau of Mines for July 1940.

Almost all strategic mica is consumed in the production of aircraft and tank magnetos, spark plugs, military radios, and sound-detection equipment.

Urgently needed strategic grades of Indian mica have been im-

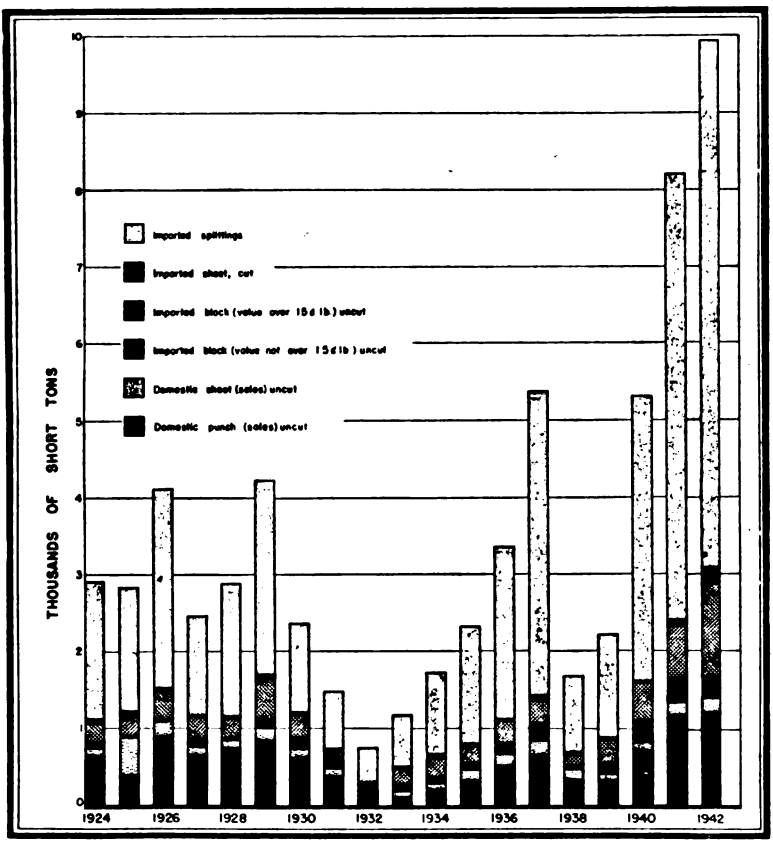

FIGURE 2.—Block and sheet mica (cut) and splittings imported for consumption in the United States, and sales of domestic sheet and punch mica, 1924–42.

ported by air since September 1942. Conservation orders and shortages of materials for commodities that were manufactured chiefly for civilian consumption curtailed the demand for splittings and enabled industry and the Government to accumulate adequate stock piles of muscovite and phlogopite splittings.

In 1942, as in 1941, condenser mica was in greatest demand; and as demand outgrew production and import of the better grades, the quality of the mica allocated for this use was lowered to include good-stained material.

Figure 2 summarizes graphically the situation with respect to imports and domestic production. As reported by the Mica-Graphite

Digitized by Google

Division of the War Production Board, good-stained and better comprise about 60 percent of all imports, and sizes 5, 5½, and 6 of both imported and domestic material are in greatest demand. Stocks of good-stained and better at the end of the year were sufficient for 8½ months at the average rate of consumption in 1942, although stocks of specific size groups ranged from 11 to only 2.8 months' supply. Domestic production furnished approximately one-tenth of the total new supply for the year of good-stained and better and one-eighth of all qualities. However, with the improvement in trimming, as well as increase in production, it is expected that the percentage of the total supply furnished by domestic production will increase.

MICA SPLITTINGS

Consumption of splittings fell below the record high of 1941, and Government stocks increased from 4,928,000 pounds on January 1, 1942, to 11,374,000 pounds by the end of the year. Industrial stocks remained relatively constant although slightly below the 1941 level. The decline in total consumption of splittings, which began in the third quarter of 1941, continued through the first quarter of 1942. However, beginning with the second quarter of 1942 and throughout the rest of the year the consumption of splittings, muscovite and amber combined, increased. Consumption of amber splittings alone reached a peak in the second quarter of the year and then declined gradually throughout the rest of the year, whereas the consumption of muscovite splittings increased in each quarter.

Grade 6 loose splittings, which are produced in three qualities—first, second, and third—constituted 81 percent of the total consumption of muscovite splittings during the fourth quarter of 1942. In the corresponding quarter of 1941 this size made up 80 percent of the total. Nearly equal amounts of first- and third-quality splittings were consumed, but consumption of No. 2 quality was greater than that of Nos. 1 and 3.

Consumption and stocks of mica splittings in the United States, 1938–42, by sources, as reported by the consumers

Year	India		Canada		Madagascar		Total	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value

[1] Exclusive of a nominal quantity of splittings produced in the United States and South America.

Before 1942, production of splittings in the Western Hemisphere was confined largely to phlogopite splittings produced by hand in Canada and small quantities of phlogopite imported from Canada and

Digitized by Google

split mechanically in the United States. However, in 1942 splittings were produced in Mexico from block mica, most of which originated in India and Brazil.

The table of imports for consumption in 1942 includes 6,720 pounds of splittings imported from Japan. This is part of a shipment received in the foreign-trade zone at Staten Island in 1940

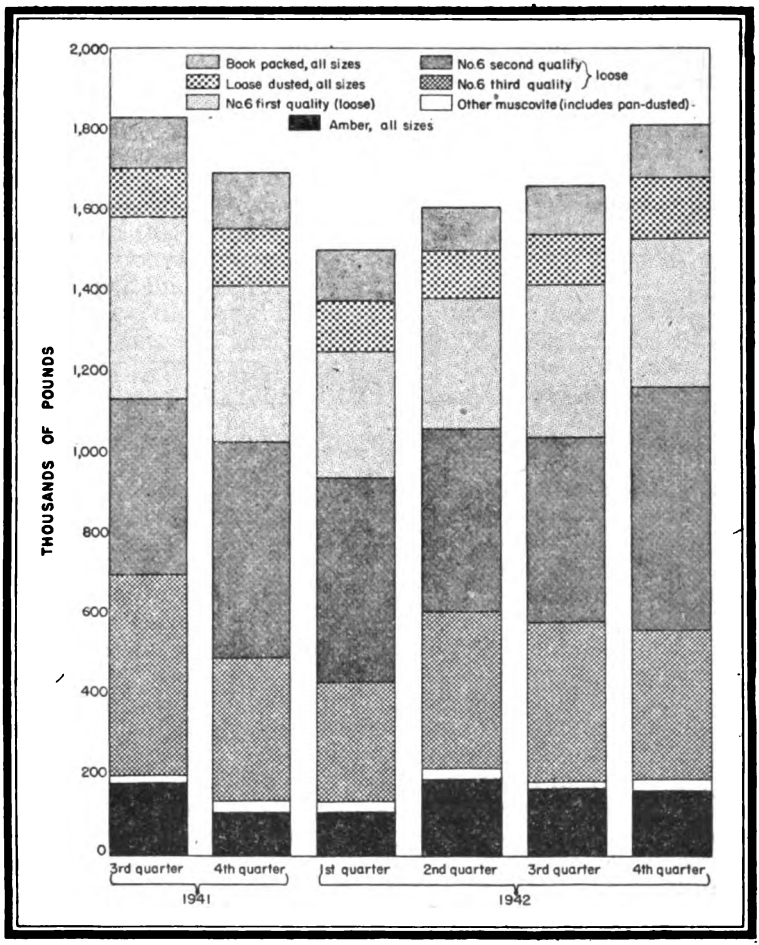

FIGURE 3.—Consumption of specified sizes and qualities of mica splittings in the United States, by quarters, July 1941 to December 1942.

and remained there. The 6,720 pounds represent that portion of the shipment released to the industry in March 1942.

The new 1942 supply was more than enough to meet requirements for the year. Stocks held at the end of 1942 by the Government and industry were adequate for about 3 years at the 1942 rate of domestic consumption. Consumption of splittings from July 1941 through December 1942 is summarized graphically, on a quarterly basis, in figure 3.

BUILT-UP MICA

Curtailment in the manufacture of electrical appliances and other consumers' durable goods, together with restrictions imposed on mica through conservation orders, caused the demand for built-up products to decline in the latter half of 1941 and the first quarter of 1942. However, as production of military equipment increased, demand for this material rose, particularly for making certain electric-generator and motor parts in which it is the standard irreplaceable insulating material. Consumption of built-up mica, therefore, began to increase after the first quarter and continued to do so during the remainder of the year.

Built-up mica produced in the United States, 1941–42, by kinds of product [1]

Product	1941		1942	
	Pounds	Value	Pounds	Value
Molding plate	1,874,000	$1,854,000	1,599,000	$1,552,000
Segment plate	2,317,000	2,599,000	2,045,000	2,367,000
Heater plate	539,000	789,000	212,000	303,000
Flexible (cold)	706,000	754,000	649,000	743,000
All other (tape, etc.)	1,199,000	2,089,000	1,628,000	2,794,000
	6,635,000	8,085,000	6,133,000	7,759,000

[1] Partly estimated.

POSSIBLE SUBSTITUTES

Every effort is being made to conserve our supplies of high-grade sheet mica by stipulating use of the smallest possible sizes, by requiring use of lower qualities wherever possible, by minimizing spoilage and wastage, and by finding substitutes.

Under rules established by the American Institute of Electrical Engineers, mica is not required in class "A" insulation but has been used to a considerable extent because of a greater margin of safety with particular reference to heat and fire resistance. In induction motors, varnished cloth has been substituted for mica, and a cloth-base, phenolic, laminated compound has been substituted as insulation between the decks of strip-wound commutating field coils. Such substitutes may serve in particular applications as indicated, but a substitute for the high-grade mica now required in certain types of military equipment has not been found. Several promising new materials are in process of development, and although each has characteristics similar to those of mica, none possesses the particular combination of characteristics enjoyed by mica. The War Production Board estimates that substitutes, when and if they are fully developed and approved by the Armed Services, may replace 10 to 15 percent of the mica now required in certain fields. However, none of the substitutes for high-grade mica have yet passed the laboratory stage.

PRICES

Mica is marketed in a confusing variety of sizes (grades) and classes (qualities) ranging in value from a fraction of a cent a pound for small, stained, imperfect flakes or scrap to over $20 a pound for exceptionally large, flat, clear, crystal sheets. Not only does marketable mica vary greatly in size, from small punch to 8 by 10 inches and larger, but for each grade there are at least nine different qualities, ranging from clear to black-stained.

Digitized by Google

Prices for Indian mica were raised because of increasing cost of insurance and ocean transportation. Prices for domestic punch and circle mica were increased in an effort to stimulate domestic production. These two classes were chosen on the theory that since they represented the bulk-line product, an increase in the price of these classes would afford the maximum encouragement to miners. However, this was not satisfactory because the value of the other sizes increased and that of punch and circle mica remained stationary.

The Colonial Mica Corporation, agent for the Metals Reserve Co., then set up a schedule of prices they would pay miners for strategic grades of mica. Mica thus purchased was allocated to processors and manufacturers at the current market price. To get the maximum amount of strategic material, this corporation also bought nonstrategic mica or assisted miners in marketing this low-grade material.

The price scale on which Colonial Mica purchased strategic mica was a base price only. Mica poorer than No. 1 grade was subject to a discount from this scale, the exact amount of which depended on the judgment of Colonial Mica Corporation buyers. The base price was revised several times during the year.

It was hoped that production of nonstrategic grades of mica would increase with increase in strategic grades, but most miners brought in only the highest-price material, leaving the lower-grade sheet, punch, and scrap on the mine dumps. Therefore, on November 19, 1942, new maximum prices for nonstrategic punch and sheet mica were issued by the Office of Price Administration under Order No. 141, section 3 (b), of the General Maximum Price Regulation. They ranged from 12 cents a pound for punch to $2 per pound for sheet mica 6 by 8 inches. This step failed to remedy matters, which became so acute by January 1943 that several mica grinders were forced to close their plants temporarily. A meeting of industrialists and representatives from the Office of Price Administration was called by the War Production Board, and the scale of prices for nonstrategic grades of mica was revised in an effort to relieve the fast-developing shortage. The new scale was released on March 20, 1943, by the Office of Price Administration. Nonstrategic punch and sheet mica, scrap mica, and crude mica schist were removed from price control. The maximum price of domestic ground mica, mica schist, water-washed mica, and micronized mica was raised $5 per short ton.

Trade-journal quotations and average sales value of domestic uncut sheet mica per pound in 1942

Size	Trade-journal quotations [1]		Average value [2]	
	Dec. 18, 1941	Dec. 3, 1942	Clear	Stained or spotted

FOREIGN TRADE [1]

Imports.—In 1942, total imports of all kinds of mica increased to 11,280 short tons valued at $9,044,875, compared with 8,300 tons valued at $4,415,031 in 1941. This was spread over all grades of mica. Waste and scrap phlogopite imports nearly doubled, and those of untrimmed phlogopite increased 41 percent. The higher grades of sheet mica also increased substantially. Further details on imports, by kinds and sources of origin, may be found in the following tables.

Exports.—Exports of both unmanufactured and manufactured mica were lower in 1942 than 1941, owing to greater requirements of our war industries and the shortage of shipping space.

Mica imported for consumption in the United States in 1942, by kinds and by countries

Country	Unmanufactured

WORLD PRODUCTION

Aside from India, where the military situation and transport are the chief problems and their future status is unpredictable, our foreign supplies have come largely from Brazil. New sources are being developed, and particular efforts are being made to expedite production in India and Brazil. The Board of Economic Warfare has sent specialists and engineers to the other Americas in search of new deposits and to advise local producers on mining and preparation of mica for marketing. The following table shows world production by countries from 1937 to 1942 so far as statistics are available.

World production of mica, 1937–42, in metric tons [1]

Argentina.—All of the mica produced is muscovite and is classified as 80 percent stained and 20 percent clear. However, only about 5 percent is clear mica by Indian standards of grading. The United States and the United Kingdom of Great Britain and Northern Ireland received all exports of mica from Argentina in 1942. In 1940 and 1941, Japan, Germany, and Italy imported large amounts of Argentina mica. Japan took all classes and grades, but Germany and Italy imported only the stained and better grades. A large proportion of the Italian quota in 1941 was sent to that country by airplane; it has been reported that the ship carrying most of the German imports for 1941 was intercepted by the British.

Australia.—Production has been limited almost entirely to muscovite from deposits in Northern Territory. Small quantities for grinding have been produced in Queensland, New South Wales, South Australia, and Western Australia. Most of the splittings come from India, although there is a small domestic splittings industry. In 1941 the Minister of Trade and Customs acquired all mica produced in Northern Territory, and in 1942 control and distribution of mica passed to the Comptroller of Mineral Products. Prices are fixed by the Commonwealth Price Commission. Consumption of clear and slightly stained mica increased in 1942, and it was necessary to import mica to satisfy domestic demands.

Brazil.—Mica comes chiefly from eastern Minas Gerais, although a small quantity of good-quality material also is mined in Baía and São Paulo. Mining methods are primitive, and considerable effort has been made to increase production by applying more efficient methods of mining and transportation. In 1942 Brazil exported 866 metric tons of mica, of which the United States received 776 tons and the United Kingdom the remainder.

Canada.—Canada, which has been one of the two important world sources of phlogopite mica, entered the field of muscovite producers in 1942. Extensive deposits of white mica have been found near Eau Claire, Nipissing County, Ontario.

Arrangements have been completed between the United States and Canada for the Colonial Mica Corporation of New York to act as sole buyer of the strategic grades of mica from these properties. The production of phlogopite mica was essentially the same as in 1941.

Ceylon.—Here the right to mine mica is sold by authorized Government agents, and the areas must be approved by the Government mineralogist. Charges for mining are to be 5 percent of the value of the mica removed. The entire output for 1942 was bought by the British Ministry of Supply for use by the United Nations Joint Mica Commission.

India.—India is the most important producer of strategic mica (muscovite sheet and splittings), supplying about 75 percent of total world production of this grade. The producing areas are concentrated chiefly in the eastern part of the country, although a few small phlogopite deposits in the Travancore district of southwestern India are being developed.

Indian block mica has been shipped chiefly to the United Kingdom and the United States, the two countries at times having taken three-fourths of the total of such exports even before the war. Japan bought heavily from India up to 1940, when an unofficial but effective embargo was placed against such shipments. It is believed that

Digitized by Google

a large portion of Japanese purchases was for reshipment to Italy and Germany. During the first quarter of 1941 only enough low-grade mica was shipped to Japan to prevent official protests, and in July 1941 the embargo, still not announced, again went into effect. At the same time restrictions on shipments of mica to the United States were relaxed to the extent of omitting inspection of shipments at the mine, which simplified procedure and provided for quicker and more efficient handling.

Exports of mica from India in 1942 (which are the only available measure of production), as reported by the Bureau of Foreign and Domestic Commerce, were 14,398 metric tons, of which 13,155 tons were block and splittings and the remaining 1,243 tons consisted of ground, scrap, or waste. The United States received 5,451 metric tons of the Indian production, the United Kingdom of Great Britain and Northern Ireland 8,809 tons, and Australia and the other Allied Nations the remaining 138 tons.

Madagascar.—Madagascar continued as the largest source of strategic phlogopite mica, but the United States received imports only in March and April. The principal deposits are in the extreme south end of the island. However, because of adequate stocks and restricted use, there was mica enough of this type to satisfy present requirements and to maintain an adequate stock pile.

Mexico.—Mica has been produced in Mexico for only a relatively short time, although the existence of deposits has been known for a long time. Most of the deposits are of the phlogopite variety, although some biotite and muscovite also have been found. Production for the latter half of 1942, the only period for which statistics are available, was 44 metric tons of phlogopite, all of which was exported to the United States.

New Zealand.—Muscovite-mica deposits of considerable size were discovered in south Westland (west coast of the South Island) at an altitude of 4,000 to 5,000 feet. Samples were of excellent quality, and access roads are being constructed, as there is an assured though small domestic market for the finished product.

Peru.—Mica is the youngest mining enterprise in Peru, where deposits have been found along the Pacific coast and have been developed in an area 14 miles long by 7 miles wide. It has been estimated that with present mining equipment, plus access roads and trucks, 20 tons of trimmed mica can be produced monthly.

Portugal.—Production in Portugal is mainly scrap mica from numerous small deposits and a small amount of good-quality amber sheet mica in small sizes. The estimated annual production is 350 short tons of scrap and 40 tons of amber sheet.

U. S. S. R.—Information on production of mica in the U. S. S. R. is very meager. Production statistics have not been available since 1935. Deposits are widely distributed and have been found in Archangel (Karelia), on the Kola Peninsula, in the Volyn provinces on the Black Sea coast, in the Urals, and in Siberia. The Siberian deposits in the Mama River district, the northern Baikal region, and Transbaikalia are said to furnish the major portion of the muscovite production. It is estimated that the Soviet Republic produces enough mica to meet its requirements.

Rock salt	1479	Imports and exports	1486
Evaporated salt	1479	World production	1488
Pressed blocks	1480		
Salt content of brine	1480		

SUMMARY

Salt has contributed substantially to the war program; and, as might be expected with intensification of the war, a high record of production was attained in 1942, although the increase over 1941 was not nearly so great as that of 1941 over 1940. Gains occurred in all three types of salt output, the greatest being in salt of brine—9 percent; output of rock salt gained 7 percent and evaporated salt 6 percent. The increase in total salt was 8 percent. Demands of the chemical industry and for the manufacture of magnesium metal caused the largest increases in output of salt in 1942.

Salient statistics of the salt industry in the United States, 1935–39 (average) and 1940–42

	1935–39 (average)	1940	1941	1942
Sold or used by producers:				
Manufactured (evaporated)—short tons	2,507,374	2,782,741	3,330,106	3,517,832
In brine—do	4,205,587	5,311,671	6,771,436	7,373,165
Rock salt—do	1,947,254	2,265,548	2,619,087	2,802,287
Total:				
Short tons	8,660,215	10,359,960	12,720,629	13,693,284
Value [1]	$23,405,612	$26,474,619	$33,620,376	$38,144,234
Average per ton [1]	$2.70	$2.56	$2.64	$2.79
Imports for consumption:				
For curing fish—short tons	[2] 21,250	[2] 12,965	7,426	[2] 6,434
Value	[2] $43,722	[2] $25,174	$30,058	[2] $17,667
In bags, barrels, etc—short tons	1,385	1,024	1,110	367
Value	$11,813	$6,601	$12,156	$4,138
In bulk—short tons	24,131	16,413	6,896	953
Value	$55,876	$59,029	$17,021	$7,496
Total:				
Short tons	46,766	30,402	15,432	7,754
Value	$111,411	$90,804	$59,235	$29,301
Exports:				
Short tons	90,214	147,044	123,195	118,424
Value	$521,652	$699,340	$807,925	$892,160
Apparent consumption [3]—short tons	8,616,767	10,243,318	12,612,866	13,582,614

[1] Values are f. o. b. mine or refinery and do not include cost of cooperage or containers.
[2] Includes salt in bags, sacks, barrels, or other packages—1938: 93 tons valued at $673; 1940: 6 tons, $12; 1942; 122 tons, $1,200.
[3] Quantity sold or used by producers plus imports minus exports.

Of the dry salt produced in the decade 1932–42, evaporated salt has averaged 56 percent and rock salt 44 percent of the annual totals, the proportions having been maintained rather consistently throughout the period.

Increased demand was experienced not only by the largest producers but also by many of the smaller operators, who reported active demand throughout the year. Wage increases ranged from 10 to 50 percent. No strikes were reported, but labor was scarce, particularly in the less-populated areas. Cost of material was reported to be high; in one locality the price of bags increased 300 percent. Many operators, particularly the smaller, stated that rising wages and costs of materials handicapped their business, inasmuch as the selling price was unchanged. Several plants closed, temporarily at least, the time of reopening to depend on the ability to obtain labor and on the selling price.

PRODUCTION

Salt was produced in 86 plants of 64 companies in 1942, operating in 14 States and Puerto Rico, compared with 83 plants of 65 companies in 1941. Of these plants, 66 produced evaporated salt and 20 rock salt; 11 of the plants in 7 States produced all the brine.

The International Salt Co. leads in rock-salt production as well as in total dry salt output. Morton Salt Co. leads in output of evaporated salt and is second in total dry salt production. Leslie Salt Co. is the largest producer of solar salt. Morton Salt Co. has some rock-salt interests, and International Salt Co. also produces some evaporated salt.

States.—Michigan again led in total production of salt as well as in output of the evaporated type, and New York led in rock-salt production; together, these States supplied 49 percent of the Nation's output of commercial salt. Grouped as a section, the Middle West (Kansas, Michigan, and Ohio) supplied 55 percent.

Methods of manufacture.—As in the past, the salt was obtained from natural brine of wells and ponds, by forcing water into salt beds and withdrawing it as brine, from sea water, and from bedded deposits that are mined. Salt is evaporated by several methods, as given in the accompanying table.

Salt sold or used by producers in the United States, 1941–42, by methods of manufacture

Method of manufacture	1941		1942	
	Short tons	Value	Short tons	Value
Evaporated:				
Bulk:				
Open pans or grainers	501, 236	$4, 100, 293	500, 758	$4, 607, 104
Vacuum pans	2, 192, 142	12, 596, 983	2, 234, 633	13, 916, 501
Solar	454. 397	1, 577, 740	542, 087	2, 238, 604
Pressed blocks	182, 331	1, 505, 040	240, 354	2, 228, 062
Rock:				
Bulk	2, 562, 386	8, 300, 562	2, 734, 797	9, 054, 447
Pressed blocks	56, 701	461, 265	67, 490	569, 014
Salt in brine (sold or used as such)	6, 771, 436	5, 078, 493	7, 373, 165	5, 530, 502
	12, 720, 629	33, 620, 376	13, 693, 284	38, 144, 234

Rock salt.—The output of rock salt came from 20 plants in 8 States, chiefly New York, Louisiana, Kansas, Michigan, and Texas, in order of output; California, New Mexico, and Utah also produced.

Rock salt sold by producers in the United States, 1938–42

Year	Short tons	Value	Year	Short tons	Value
1938	1, 901, 861	$6, 252, 081	1941	2, 619, 087	$8, 761, 827
1939	2, 035, 157	6, 496, 807	1942	2, 802, 287	9, 623, 461
1940	2, 265, 548	7, 384, 839			

Evaporated salt.—Sixty-six plants in 13 States and Puerto Rico supplied evaporated salt, as given in the accompanying table, compared with 61 plants in 12 States and Puerto Rico in 1941.

Evaporated salt sold or used by producers in the United States, 1941–42, by States

State	1941		1942	
	Short tons	Value	Short tons	Value

Pressed blocks.—Hydraulically compressed blocks from both evaporated and rock salt totaled 307,844 short tons valued at $2,797,076 in 1942. They were produced by 8 rock-salt and 20 evaporated-salt plants.

Some of the blocks for domestic consumption contain small amounts of chemicals for their medicinal value. Blocks of iodized salt are produced for conditioning cattle, although the demand for salt of this type is not nearly so great as for those to which sulfur and other chemicals have been added. Some of the blocks contain potassium. At one of the potash mines where salt is a byproduct sold to another company for distribution, some of the salt, which contains about 20 percent potash, is made into blocks simply by pouring a strong brine over a boxful of the salt, which has been ground to ¼-inch mesh and under. When dry the blocks are too hard to be broken by hand, although they will disintegrate when out of the boxes and exposed to weathering and must be sold in the containers.

Pressed-salt blocks sold by original producers of the salt in the United States, 1938–42

Year	From evaporated salt		From rock salt		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1938	136,699	$1,116,272	36,258	$281,109	172,957	$1,397,381
1939	152,121	1,136,527	39,242	263,300	191,363	1,399,827
1940	152,267	1,193,237	40,171	282,435	192,438	1,475,672
1941	182,331	1,505,040	56,701	461,265	239,032	1,966,305
1942	240,354	2,228,062	67,490	569,014	307,844	2,797,076

Salt content of brine.—Salt in brine produced at 11 plants in various parts of the country increased from 6,771,436 short tons in 1941 to 7,373,165 tons in 1942. Most of the brine was used as the source of basic chemicals. The Federal Reserve Board index for chemicals rose from 137 in 1941 to 173 in 1942.

STOCKS, SEASONAL DEMANDS, AND CAPACITY FOR PRODUCTION OF COMMERCIAL SALT

In general practice, salt producers do not attempt to keep large stocks on hand. However, the practice varies somewhat according to the types of salt sold.

Most evaporated salt is shipped as rapidly as it is refined and packed. The plants have bins only to accommodate near-future requirements to guard against temporary delays from interruptions in their plants. At those evaporated-salt plants where storage is provided, it is reported that the bins have a capacity of only 1,000 to 6,000 tons, which may represent requirements for only 4 or 5 days, or at the most a month's supply.

A notable exception is the storehouses on the shore of Lake Michigan, where several plants stock their salt in the winter awaiting water transportation. Here the supply may total 10,000 to 40,000 tons of evaporated salt stored during the off-peak shipping season.

Solar salt presents a somewhat different problem. Here the salt necessarily must be stored in great piles in the open. For climatic reasons, solar salt is harvested from ponds chiefly in the last 3 months

Digitized by Google

of the year. The salt, stacked in huge piles, the steep sides of which become crusted and impervious to rain, represent 9 to 11 months' supply.

Rock-salt producers find that the best and cheapest way to store salt is in the ground, and surface stocks are virtually nonexistent. Therefore, at most mines the salt either is shipped out as rapidly as it is mined, crushed, and screened, or "finished," or it is blasted down in a room in the mine and left there until needed above ground. Such underground piles may be enough for 6 to 8 months' supply. One of the mines that normally in the past had about 35,000 tons of various grades shipped the salt in 1942 as mined. Surface bins are merely for loading, and the salt may be in them only 4 or 5 days or less. One operator that "stores" in the mine has loading bins of about 1,000 tons, which is less than a day's production. Exceptionally small bins of 100 to 250 tons capacity are maintained to store various sizes of the screened rock salt to satisfy demands for sizes not being made currently.

In the matter of seasonal demands, most salt producers say that in the second half of the year the demand for both evaporated and rock salt is heavier than in the first half. Some have slightly higher demands in the spring and fall but not enough to affect their supplies appreciably.

A Bureau of Mines study reveals that plant capacity for rock-salt production totals about 5,200,000 tons and for evaporated salt about 4,400,000 tons. Therefore, it is evident that in 1942 the rock-salt facilities operated at 54 percent and evaporated salt at 80 percent of capacity. (These capacities are predicated on well-ordered production systems and do not make allowance for idleness during break-downs, delays in obtaining critical materials for repairs, or other causes.)

Theoretically it is easier to expand the capacity for rock salt than that for evaporated salt, as it becomes chiefly a matter of how speedily the loose material can be hoisted to the surface.

In some solar salt playas and marshes there is an unlimited supply of crude salt that requires only loading. Most of these, however, are not near marketing centers or shipping points, and the transportation makes a commodity costly that is very cheap at the source.

RESOURCES

Fortunately for the United States, when it is involved in a war that depends so much on chemicals in one form or another, the country has an inexhaustible supply of salt and a well-established chemical industry.

The Middle West has huge underground stores of salt within three of its States. Kansas has many millions of tons in reserve. Michigan has deposits in three separate sections; wells annually supply thousands of tons of strong salt brine, and in addition there are rock-salt mines. Ohio has no rock-salt mines, but it apparently has a plentiful salt supply although the brine raised is not as strong as that of Michigan.

The Pacific coast depends largely on the ocean, and therefore its supplies of solar salt are unlimited. Additional resources in California are the desert playas and rock-salt deposits.

556250—43——94

Digitized by Google

In the South the huge domes of almost pure salt in Louisiana and Texas can supply requirements for a long time. The domes usually range from 1.2 to more than 2 miles in diameter and are thousands of feet in thickness.

The East, although not destitute of salt, is the least fortunate of all sections of the United States. New York, the leading source, has large deposits of rock salt that yield mined salt and brine for making chemicals and evaporated salt after recrystallization. However, these sources are about 200 miles inland. In the past the eastern seaboard has obtained salt from Canada and the West Indies; but, with difficulties in shipping because of the war, imports from these former sources have dwindled in the past few years. The western part of Virginia has supplies of natural brine, which is used solely for the manufacture of chemicals. West Virginia has resources of brine from which it produces evaporated salt.

Some States have large deposits of good salt, but economic conditions do not favor their development. For instance, New Mexico has numerous salt deposits but only a few small, scattered plants to supply local demands. Enormous reserves are present, but no large-scale consuming industries are near enough to encourage development.

DISTRIBUTION AND CONSUMPTION

Although the figures in the accompanying table cover original shipments from the producers and do not show reshipments, they indicate approximate salt consumption in the various States.

Distribution (shipments) of evaporated and rock salt in the United States, 1941–42, by States of destination, in short tons

Destination	1941		1942	
	Evaporated	Rock	Evaporated	Rock
Alabama	7,613	32,790	8,432	58,835
Arizona	10,350	3,031	11,814	2,673
Arkansas	9,262	26,968	8,011	28,144
California	275,417	29,594	277,696	54,578

Wisconsin	132,958	25,743	129,307	26,553
Wyoming	6,763	1,768	7,755	2,073
Other [1]	86,953	76,881	56,353	81,355
	3,330,106	2,619,087	3,517,832	2,802,287

[1] Includes production of Puerto Rico (evaporated salt); exports to Africa, Asia, Canada, Central America, Mexico, Newfoundland, South America, West Indies, and other countries; shipments to Alaska, Hawaii, Puerto Rico, and Virgin Islands; and some shipments to unspecified destinations.

Salt shipped to noncontiguous Territories of the United States, 1941–42

Territory	1941		1942	
	Short tons	Value	Short tons	Value
Alaska	5,929	$103,455	4,829	$94,646
Hawaii	2,909	78,996	2,668	109,222
Puerto Rico	1,629	50,046	1,004	34,100
Virgin Islands	32	1,775	53	3,562

Consumption trends have changed in the last few years, owing in part to the shift of consumers from one center to another and in part to the establishment of entirely new centers of consumption. The average annual shipments for 1931–36 show that New York received the largest total of dry salt of the two types; Illinois was next in receipts, followed by California, Michigan, Texas, and Kansas. In the evaporated-salt market, Illinois received the largest average annual total in 1931–36, followed by California, Michigan, New York, Texas, and Kansas. In rock-salt receipts, New York led, followed by Illinois, Kansas, Texas, Michigan, and California.

USES

Our first full year of war witnessed an increased use of salt for all the war purposes discussed in the chapter on Salt in Minerals Yearbook, 1941; and in addition there were a few new and modified uses, both military and civilian.

Less salt was used for industrial meat packing in 1942 than in 1941, chiefly because of greater demand for canned instead of salt-treated meat for camps at home and overseas. Also, more meat was packed and canned on the farms in 1942. Although canning requires less salt than packing, about 10,000 tons more salt were used in industrial

Digitized by Google

canning. Home canning of various products made greater demands also, as evidenced by the large increase in table salt and other household uses.

Chemicals were made not only from brine but from thousands of tons of "dry" salt as well. Chemicals from salt have long been used in many medicines, and recent uses include the groups of sulfa and vitamin drugs.

Both elements of salt are used in many of our war materials, as exemplified by the following: Both sodium and chlorine are needed in making tetra-ethyl lead for high-octane gasoline, production of which increased enormously in 1942. Sodium and chlorine are being used increasingly for synthetic-rubber manufacture. Many dyestuffs require both. Cotton linters for smokeless powder are treated with chlorine for bleaching and sodium for purifying. The cleaning and degreasing of metal tools, parts, and shells require both elements.

Fighting in the hot jungles has created a new application for salt and derivatives thereof. Chlorine is an effective spray for eliminating mosquitoes and other jungle insects. The men fighting in the tropics are supplied with salt tablets to combat heat cramps caused by loss of salt through perspiration. Also, Navy regulations provide for salt to be supplied to the men on ships, needed by men not only when in tropical waters but when working below decks in the hot engine rooms.

As a result of wartime requirements, chlorine output in 1942 was greater than it has ever been; even with the curtailment of civilian supplies, it exceeded the 1941 output by more than 30 percent. Because of lack of steel containers in which chlorine is "packaged" and tank cars to transport it, the chemical cannot be stocked ahead of the demand, and the suppliers must keep a watchful eye on requirements and prompt return of the containers.

Salt sold or used by producers in the United States, 1941–42, by classes and uses, in short tons

Use	1941			1942

For many years most of the chlorine produced in the United States has originated in New York State. Little more than a decade ago New York still produced about half of the national output, and Michigan and Ohio were large producers also. The trend has changed, and in recent years the Midwest has become the largest chlorine-producing center, and new plants are to be found in the South and West. To the many uses for chlorine mentioned in the Salt chapter for 1941 may be added smoke screens and smoke bombs. Additional quantities of chlorine compounds were used in plastics, special water- and mildew-proofing waxes, fire extinguishers, and disinfectants.

With a view to utilizing some of the vast salt deposits in Kansas for chlorine and the petroleum from nearby oil fields for cheap power for steam generators, investigators (George W. Stratton and Delos E. Winkler) at the University of Kansas developed a method of making carbon black from natural gas and chlorine.[1] From 1,000 cubic feet of the mixture, it is said, 30 pounds of carbon black are produced. The process is not yet commercial.

Sodium compounds derived from salt have many important uses in the form of soda ash and caustic soda; the largest use for soda ash is in glassmaking, and for caustic soda in rayon-fabric manufacture. Sodium compounds will also assist in the removal of unwanted sulfur compounds from petroleum products and are essential raw materials for phenolic resins. They assist not only in making rayon cord for rubber tires but are used also to dissolve the cord fabric in the tires when the rubber is to be reclaimed.

Increases in output of magnesium metal made by methods that require large tonnages of salt led to corresponding increases in salt production in 1942.

The use of common salt for glazing ceramics has increased in the last year or two, because of the increased use of such ware for cooking utensils, structural building units, and other purposes, and because salt is said to be the simplest and cheapest of all glazes.

Statistics show that the use of salt on roads is continuing. It is applied mainly to secondary roads where the salt is bladed into the clay or gravel of the top layer. Emphasis has been placed upon the advantage of such roads in cold weather or during seasonal changes in temperature. In Cuba in 1942 salt was used on runways of air fields. It was added to the layer of clay and gravel under the top dressing of asphalt to make it more elastic and thus obviate cracking. Usually in the United States salt-treated roads have no top dressing, although a successful long-used road in Virginia was made by finishing with a thin layer of asphalt over the salt-treated layer.

Further interest in salt as a fertilizer for beets and mangolds was created by articles in the press [2] which advised all growers of beets on muck soil to make every acre produce its best in 1942 by applying 1,000 pounds of salt an acre in addition to the regular fertilizer used. It is claimed that 500 to 1,000 pounds of salt so applied may increase the yield from 13 tons to 21 tons an acre. Salt has also been utilized instead of potash on mangolds, sugar beets, and cabbage at the rate of 500 pounds an acre. Moreover, when employed in conjunction with a good dressing of sulfate of ammonia, salt is said to act as well

as muriate of potash. Sandy soils (often deficient in potash) are said to be improved by its application; salt has also proved most effective on light and medium soils.

CHANGES IN THE INDUSTRY

The plant of Oklahoma Salt Industries, Inc., which began producing in 1941 at Sayre, Okla., suffered heavy loss by fire and was out of operation after September 26, 1942; it is being rebuilt. The Stauffer Chemical Co., which sold its solar salt works at Redwood, Calif., to the Leslie Salt Co. the latter part of 1940 but continued to operate in 1941, did not produce in 1942. The Leslie Salt Co., San Francisco, has enlarged its solar-salt fields on the Pacific coast and in 1942 also produced from a deposit of rock salt at Fallon, Nev. The Mullet Island Salt Co., Niland, Calif., began producing in 1942; and the Defense Plant Corporation, at Death Valley Junction, Calif., produced solar salt for 3 months of 1942. The Puerto Rico Salt Works, Inc., Mayaguez, P. R., reported in detail its three plants in Guaypao, Boqueron, and Llanos Costa Counties, instead of including them in a consolidated report as formerly. Works of Marcelino Ramos, Ensenada, P. R., made no sales in 1942. In March 1943, the Morton Salt Co., Chicago, bought the Worcester Salt Co., which operated an evaporated-salt plant at Silver Springs, N. Y.

IMPORTS AND EXPORTS[3]

From 1938 to 1942 imports averaged about 0.25 percent and exports a little more than 1 percent of production. Most of the imports are received on the Atlantic coast, where no salt plants operate.

In normal times pressed blocks have not been exported, but since lend-lease has been in effect some shipments of blocks have been made overseas. This is not apparent, however, in the accompanying table, as the exports are not shown by classes.

Salt imported for consumption in the United States, 1938–42, by classes

Year	In bags, sacks, barrels, or other packages (dutiable)		Bulk			
			Dutiable		Free (used in curing fish)	
	Short tons	Value	Short tons	Value	Short tons	Value
1938	654	$8,228	17,849	$45,897	[1] 21,010	[1] $47,800
1939	2,121	14,977	28,451	58,540	15,461	27,700
1940	1,024	6,601	16,413	59,029	[1] 12,965	[1] 25,174
1941	1,110	12,156	6,896	17,021	7,426	30,058
1942	[2] 367	[2] 4,138	953	7,496	[1] 6,434	[1] 17,667

[1] Includes salt in bags, sacks, barrels, or other packages as follows—1938: 93 tons valued at $673; 1940: 6 tons, $12; 1942: 122 tons, $1,200; 1939 and 1941: None reported.
[2] Includes 98 pounds valued at $3 imported into Alaska free for the U. S. Government.

[3] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

WORLD PRODUCTION

Salt production in the United States represents roughly about one-third of the global production. It does not figure largely in international trade until converted into products. In the last decade the United States has doubled its output. The war has had its effect on a number of other countries. Salt production in Canada increased 17 percent in 1942 compared with 1941, part of the increase being attributed to greater demand for chemicals, especially chlorine. Free China produced 800,000 metric tons of salt during the first 9 months of 1942 and 1,152,000 tons in the year 1941. Statistics for occupied China have not been available for the last 2 years, but the salt fields have been worked actively. In 1941 Germany established a compulsory national salt cartel comprised of one rock-salt and two evaporated-salt associations. The Italian Empire has suffered important salt losses through the war, first, by the loss of its East African colonies, later by the loss of Libya, and more recently through damage done by bombings of the salt works near Trapani, Sicily. In accordance with an agreement made in September 1942, Spain is to supply French Morocco with salt in exchange for phosphates from the latter country.[4] Additional details regarding the salt industry in these and other countries have been recorded in various issues of Bureau of Mines Mineral Trade Notes—Confidential Series, between July 1942 and May 1943.

SUMMARY

War and essential civilian requirements absorbed nearly the entire output of the magnesia and natural-salines industries during 1942. Magnesia refractories were derived from magnesite, brucite, dolomite, sea water, and well brines principally to satisfy the increasing demands of open-hearth and electric steel furnaces. Caustic-calcined magnesite was used for flooring war plants and cargo ships. The total output of magnesium chloride from well brines, sea water, dolomite, and magnesite increased tremendously over production in previous years to meet magnesium-metal requirements. Consumption of calcium chloride grew in nearly all its customary uses, but particularly in freezeproofing coal and ores to facilitate unloading and release of cars. Bromine was valuable as a raw material in compounding antiknock fluids needed in mechanized warfare, and the production of iodine expanded. Sodium sulfates, carbonates, and borates were used increasingly to make glass containers, glass instruments, and structural glass—replacing metals needed for more vital war purposes.

Part I.—MAGNESIUM COMPOUNDS

MAGNESITE

The expansion in output of basic open-hearth and electric furnace steel was probably the chief single factor in the record production of raw magnesite in 1942. Magnesite and magnesia from other sources as a whole did not become critical during 1942, although shortages developed in certain of the purer grades. On their own initiative, producers undertook allocation of the scarcer grades of calcined magnesite and magnesia from sea water.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

[1] Includes caustic-calcined and refractory magnesia and magnesia from precipitated carbonate.
[2] Includes caustic-calcined and refractory magnesia and magnesia from precipitated carbonate and from magnesium hydroxide.
[3] Included under "Undistributed."
[4] Reported in Calcium Chloride section of this chapter.
[5] Includes items entered as "(3)" above.

Sales of dead-burned magnesite increased in 1942, exceeding the 1941 record. Most of the output was consumed in construction and repair of basic open-hearth steel furnaces, though some of the purer material was used in brickmaking. Imports of dead-burned magnesite, normally totaling about 35,000 tons a year, mainly from Austria, Greece, and Manchuria, declined heavily in 1942. The foreign supply pattern changed considerably, the principal source being the U. S. S. R. An impending shortage of magnesite brick was avoided by increasing the use of periclase with chromite to form the "kromag" type of brick, said to be interchangeable with or even preferable to all-magnesite brick in certain parts of open-hearth steel furnaces.

Caustic-calcined magnesite showed widely diverse adaptability to the war program. It was used chiefly in oxychloride cements for sparkproof flooring for industrial plants and interior decking of ships. Fortunately, the lower and more abundant grades of caustic-calcined magnesite (82 to 84 percent MgO before ignition) were suitable for this purpose. Oxychloride floors are particularly valuable in explosive plants and aluminum-powder plants, as their electrical conductivity prevents accumulation of electrical charges in objects being moved over the floor, thus reducing the danger of static sparking. The floors are also resistant to abrasive sparking.[2]

Digitized by Google

Magnesium metal was the next-largest direct outlet for caustic-calcined magnesite. Permanente Metals Corporation, Permanente, Calif., reduces its sea-water magnesia by the Hansgirg carbothermic process, whereas Basic Magnesium, Inc., chlorinates the calcined ore to anhydrous magnesium chloride for electrolytic reduction at Royson near Las Vegas, Nev. Substantial quantities of caustic-calcined magnesia were used as fertilizer, particularly in Florida. The synthetic-rubber industry employed high-grade magnesia derived from sea water as a catalyst and lower grades, including those obtained from magnesite, as fillers. Sea-water magnesia was also consumed in making rayon-coagulating solution. Other important uses of caustic-calcined magnesia were in fused refractory cements, glass insulators, boiler-water treatment,[8] chemical reagents, and glue.

PRICES

The maximum price of $22 a short ton for maintenance grade of domestic grain magnesite in bulk (add $4 a ton for bags or sacks, carlots), f. o. b. Chewelah, Wash., established by Order 75 of the Office of Price Administration on January 28, 1942, continued in effect throughout the year. Owing to shortages of this grade of magnesite, however, the Westvaco Chlorine Products Corporation was permitted by the Office of Price Administration to sell dead-burned grain magnesite from its stocks at Patterson and Permanente, Calif., at $32 a ton, f. o. b. Chewelah, Wash., to steel producers on the West coast, an equivalent of $40.50 a ton f. o. b. Patterson and Permanente. The shortage was relieved early in the year, but the $32 ceiling remained in nominal effect. From its Patterson (Calif.) plant, Westvaco Chlorine Products Corporation was permitted to sell dead-burned grain to the Vanadium Corporation of America and to the Mathieson Alkali Works (Inc.) at $40.50 a ton. Early in 1943 the Westvaco Chlorine Products Corporation was permitted an increase of $2.24 a short ton in brickmaking grades of magnesia shipped from Livermore, Calif. The 85-percent magnesia grade ceiling price, f. o. b. Livermore, was raised to $38.24 a short ton and the 90-percent grade to $38.74.

The following prices per ton were quoted for magnesia by the Westvaco Chlorine Products Corporation, in carlots f. o. b. California, during 1942: Caustic-calcined magnesite, bulk, $52.75; powdered, $58.75; calcined (sea-water) magnesia, bulk, $54; powdered, $60; mined periclase, bulk, 85 percent, $38.24; 90 percent, $38.74; sea-water periclase, bulk, 85 percent, $36.00; 90 percent, $36.50.

REVIEW BY STATES

California.—Johns-Manville Products Corporation, Redwood City, prepared 85-percent magnesia insulation for steam pipes and boilers, using crude magnesite as a raw material. The Marine Magnesium Corporation continued to extract high-quality magnesia for medicinal and other purposes from raw sea water at San Francisco, using the

[8] Tiger, H. L., Silica Removal [from boiler feed water] by Improved Magnesia Process: Trans. Am. Soc. Mech. Eng., vol. 64, 1942, pp. 49–63; Brit. Chem. and Phys. Abs., B, I, 1, November 1942, p. 442.

Digitized by Google

Chesny process. The Permanente Metals Corporation began production of calcined magnesia from sea water at Moss Landing, Calif., for use in its carbothermic magnesium retorts; and its affiliate, the Permanente Cement Co., shipped magnesite from Luning, Nev., for calcining at its San Jose (Calif.) kiln. Plant Rubber & Asbestos Works, San Francisco, erected a new plant at Emeryville, Calif., to make 85-percent magnesia insulation from a sea-water-bittern derivative and continued production of magnesia insulation at its Redwood City (Calif.) plant, using sea-water bitterns. Westvaco Chlorine Products Corporation mined magnesite at its Bald Eagle mine near Gustine, Calif., and at its Western mine near Livermore, Calif. This magnesite, together with that purchased from the properties of the Sierra Magnesite Co., Luning, Nev., was calcined in seven rotary kilns at Gustine, Livermore, Patterson, and Newark, Calif. Two of the Newark kilns also calcined magnesia derived from sea-water bitterns.

Nevada.—Basic Magnesium, Inc., producing magnesium metal at Royson, Nev., near Las Vegas, mined, concentrated, and calcined magnesite in 1942 at Toiyabe, Nev., north of the Luning magnesite area. The calcined material was shipped to Royson by truck and rail for chlorination and conversion to metal. The truck haul is 350 miles, but the rail route, which is quite indirect, is over 1,000 miles. Seeking to eliminate this costly rail haul and to assure an almost inexhaustible supply of magnesia, the Bureau of Mines conducted research on the recovery of magnesia from a 400,000,000-ton dolomite deposit at Sloan, 19 miles southwest of Las Vegas. The Bureau developed a process of leaching partly hydrated dolomite with magnesium chloride solution, whereby the calcium hydroxide is dissolved, leaving a magnesium hydroxide precipitate, which is filtered and calcined to magnesium oxide. The magnesium chloride needed for leaching is regenerated in a carbonation step, which simultaneously produces calcium carbonate. The two end products of the process are magnesium oxide and calcium carbonate. Bureau engineers have carried the project further by developing a method whereby the magnesia can be fed directly into the electrolytic cell.

Basic Magnesium, Inc., which is scheduled to produce eventually 112,000,000 pounds of magnesium metal annually, will require about 300 tons of magnesia daily when it attains full capacity.

Basic Refractories, Inc., Cleveland, Ohio, continued shipping brucite from the Luning area. The mineral is calcined at Maple Grove, Ohio, and is combined with stabilized dolomite to produce a grain-magnesia refractory containing about 65 percent MgO.

The Sierra Magnesite Co., owned jointly by Westvaco Chlorine Products Corporation (Newark, Calif.) and Henry J. Kaiser and his associates (Oakland, Calif.), mined magnesite from the rich Segerstrom property and other claims near Luning, the crude mineral being shipped to Newark and San Jose, Calif., for calcining.

The Bureau of Mines has published data on occurrences of magnesite and dolomite near Boulder Dam, Nev.[4]

Digitized by Google

Texas.—Meramec Minerals Co., Hanna Bldg., Cleveland, Ohio, and C. E. Heinz of Llano, Tex., continued to produce magnesite in the Llano County area.[5]

Washington.—The Northwest Magnesite Co., Farmers Bank Building, Pittsburgh, Pa., by far the largest producer of magnesite in 1942, operated the seven rotary kilns of its Chewelah (Wash.) plant at capacity during the year, producing mostly maintenance-grade magnesite for open-hearth furnaces but also shipping considerable brickmaking magnesite derived from the firm's new flotation plant. The Washington State Department of Geology reported that the Turk mine in southwestern Stevens County contains two bodies of magnesite about 500 feet apart and estimated that the two bodies contain 500,000 tons of metallic magnesium.[6]

FOREIGN COUNTRIES

Information on foreign developments in magnesite has been meager since the outbreak of the war. The latest Minerals Yearbook table showing world production by countries appeared in the volume reviewing 1939. During the 5-year period 1934–38, the U. S. S. R. produced about 534,000 short tons of crude magnesite annually, followed by Austria with 403,000 tons, Manchuria 233,000 tons, United States 157,000 tons, Greece 134,000 tons, and Czechoslovakia 83,000 tons.

Australia.—Magnesite obtained near Port Augusta, South Australia, is used in the new magnesium metal plant of the Broken Hill Proprietary Co. at Newcastle.[7]

Bahamas.—The sea-water magnesia plant under construction at Inagua by West India Chemicals, Ltd., was not completed in 1942 owing to difficulty in obtaining equipment.

Brazil.—A large deposit of magnesite in Ceara, already producing on a small scale, is said to be capable of supplying 150 metric tons of calcined magnesite monthly for export.[8]

Canada.—The Aluminum Co. of Canada, Ltd., erected a plant at Wakefield, Quebec, for the extraction of magnesia from brucitic limestone found in the area. Employing the process developed by Goudge,[9] the company calcines the rock and adds enough water to hydrate the lime, which is then removed from the magnesia granules by air separation, washing, and screening. The magnesia is delivered to Canadian Refractories, Ltd., at Kilmer, Quebec, where it is made into refractories and other products. In past years, Canadian Refractories, Ltd., and the International Magnesite Co., Ltd., have used as raw material for their basic refractories a magnesitic dolomite from Argenteuil

Digitized by Google

County, Quebec. It is reported that the former firm acquired the holdings of the latter in 1942 and will continue to produce refractory and reactive magnesias.

Cuba.—Magnesite was mined by numerous small farmers near Santa Clara, where it was caustic-calcined for export, principally to the United States.

Germany.—According to Mineral Trade Notes,[10] the Austrian and Bavarian magnesite companies have joined to form one large magnesite trust with headquarters in Berlin. The new company is styled Südost-Magnesit Ges. and has a capital of 1,000,000 marks.

Union of South Africa.—Deposits and production were reviewed in The South African Mining and Engineering Journal.[11] Reserves are estimated at not over 260,000 tons of minable material, found mostly at Burgersfort, Kaapmuiden, and in the Sutherland Range. Production is limited to a few thousand tons a year.

Venezuela.—The deposits on the Island of Margarita are said to contain over 6,000,000 tons of silica-free magnesite, and plans are under way to reopen the mines.[12]

REFRACTORY MAGNESIA FROM SOURCES OTHER THAN MAGNESITE

Particular shortages were felt in high-quality periclase for brick-making, but production of periclase by new plants in 1943 from sea water, well brines, and dolomite is expected to relieve the deficit.

Greater use of rammed dolomite-base furnace linings eliminated considerable basic brick corbeling along the front, back, and end walls of the furnaces. It is claimed that dolomite-base linings, if over 15 inches thick, can safely be rammed directly on fireclay brick and that such a bottom can be installed in less than half the time required to burn in an all-magnesite bottom, thus cutting fuel costs.

Recent developments in basic refractories were reviewed at the 25th conference of the Open-Hearth and Blast Furnace and Raw Materials Committees of the Iron and Steel Section of the American Institute of Mining and Metallurgical Engineers in April 1942 at Cincinnati. Rammed bottoms, in contradistinction to the older permanent hearth of bricks and working surface of magnesite, were shown to rebuild much faster. Bottoms of the stabilized dolomite-clinker or magnesia-chromite types are rammed a section at a time to predetermined dimensions. A layer of grain magnesite or grain dolomite may be burned in on top of the permanent hearth to serve as the working hearth, though this addition is said to be unnecessary.

The Bureau of Mines published a summary of methods for producing stabilized dolomite refractories.[13]

DOLOMITE

Shipments of dead-burned dolomite, stimulated by requirements of the steel industry, were 15 percent greater in quantity in 1942 than in 1941.

[1] Reported as "dead-burned basic refractory material."

Dolomite has long been used as a basic refractory for open-hearth maintenance and repair, averaging five to eight times the quantity of magnesite used for refractory purposes. Only recently, however, has dolomite invaded the metal field, competing with and supplementing magnesite and brines as a source of magnesium metal and compounds.

The following outline covers methods of recovering magnesium from dolomite which were either in commercial use during 1942 or to be used in plants under construction in that year.

1. Direct reduction with ferrosilicon to magnesium metal. This process is used by New England Lime Co., Canaan, Conn.; Ford Motor Co., Dearborn, Mich.; Electro-Metallurgical Co., Spokane, Wash.; Amco Magnesium Co., Wingdale, N. Y.; Magnesium Reduction Co., Luckey, Ohio; and Permanente Metals Corporation, Manteca, Calif.

2. Processes based upon the reaction $Ca(OH)_2+Mg(OH)_2+MgCl_2 \longrightarrow CaCl_2+2Mg(OH)_2$. The calcium and magnesium hydroxides are obtained by slaking calcined dolomite, and the magnesium chloride is a constituent of sea water and well brines. Calcium chloride may be added to well brines and sea-water bitterns before the milk of dolomite is added, in order to precipitate sulfate ions as synthetic gypsum (calcium sulfate), which is sold as a byproduct. If this preliminary step is not used, synthetic gypsum is precipitated to some extent with the magnesium hydroxide. The precaution is unnecessary with raw sea water, as the solution of salts is so dilute that any gypsum formed is redissolved. Permanente Metals Corporation (plant at Moss Landing, Calif.) and Northwest Magnesite Co. (plant at Cape May, N. J.) use the process to recover magnesia from raw sea water, the former for conversion to metal and the latter for refractory use; and The Dow Chemical Co. at Ludington, Mich. (plant not completed in 1942), and the Michigan Chemical Corporation, St. Louis, Mich., use (or will use) the method with well brines as the raw material, the former for metal use and the latter for refractory purposes.

3. Processes based upon the reaction, $Ca(OH)_2+Mg(OH)_2+CaCl_2+2CO_2 \rightarrow MgCl_2+2CaCO_3+2H_2O$. The calcium and magnesium hydroxides are obtained by hydrating calcined dolomite, and in present practice the calcium chloride used is a byproduct of the Solvay soda ash process. Carbon dioxide is available from the dolomite kiln gases. There are several possible variations in the process, depending on whether the end product desired is magnesium chloride or magnesium hydroxide and also on the purity and grain size of the dolomite. If the dolomite is too fine-grained it may be impracticable to recover the magnesium content as magnesium hydroxide, for the latter becomes more gelatinous and progressively harder to filter with decreasing dolomite grain size. The process is employed by the Diamond Alkali Co., Painesville, Ohio; Mathieson Alkali Works (Inc.), Lake Charles, La.; and in a pilot plant of the Bureau of Mines at Boulder City, Nev., all for conversion to metal.

Digitized by Google

4. Dolomite is calcined and washed with carbon dioxide-free water, which dissolves most of the lime, leaving magnesia undissolved. The Standard Lime & Stone Co. uses the process at its Millville, W. Va., plant, making "Sta-set" magnesia-grain refractories.

5. Milk of dolomite is carbonated, precipitating calcium carbonate, which is removed, leaving magnesium bicarbonate in solution.

(*a*) The solution is then heated, precipitating a basic magnesium carbonate. This is the Pattinson process used by Philip Carey at Plymouth Meeting, Pa.; Ehret Magnesia Manufacturing Co., Valley Forge, Pa.; Johns-Manville Products Corporation, Manville, N. J., and Waukegan, Ill.; Keasbey & Mattison Co., Ambler, Pa.; and Standard Lime & Stone Co., Millville, W. Va. Basic magnesium carbonate is used in making "85-percent magnesia" insulation for steam boilers and pipes.

(*b*) The solution is neutralized with hydrochloric acid, yielding magnesium chloride. This process is to be used by the International Minerals & Chemical Corporation, Austin, Tex., supplementing its supply of byproduct magnesium chloride from Carlsbad (N. Mex.) potash brines for conversion to metal.

6. Milk of dolomite is reacted with hydrogen sulfide, thereby dissolving the calcium as calcium bisulfide and leaving a precipitate of magnesium hydroxide, which may be filtered and calcined. The method is used by the Warner Co., Devault, Pa., for making refractory magnesia.

7. Milk of dolomite is used instead of lime in the ammonia kilns in the ammonia-soda process; ammonia is driven off, leaving magnesium hydroxide and magnesium oxide in a solution of calcium chloride. The insoluble magnesium compounds are filtered off and reacted with hydrochloric acid to yield magnesium chloride for conversion to metal. The hydrochloric acid is a byproduct of the magnesium metal cell. This so-called "acid process" is one used by the Diamond Alkali Co.

In 1942 the Bureau of Mines compiled a list of occurrences and analyses of domestic high-grade dolomite.[14]

Other aspects of the dolomite industry are reviewed in the Stone chapter of this volume.

OTHER MAGNESIUM COMPOUNDS

The production of precipitated magnesium carbonate, magnesium chloride, magnesium sulfate, and magnesium hydroxide from magnesite, dolomite, sea-water bitterns, raw sea water, well brines, and dry-lake brines in 1942 was reported to the Bureau of Mines as 362,892 short tons valued at $14,238,364, compared with 103,906 tons valued at $3,288,687 in 1941. Part of the increase in the 1942 figure is due to general expansion in output of virtually all magnesium compounds, especially magnesium chloride, and part to the inclusion in 1942 data of precipitated magnesium carbonate from dolomite, which was not included in the 1941 figures. In neither year do the figures include the magnesium sulfate derived from magnesite.

[14] Weltz, J. H., High-Grade Dolomite Deposits in the United States: Bureau of Mines Inf. Circ. 7226, 1942, 86 pp.

Digitized by Google

The production of all natural magnesium compounds, including those obtained from saline deposits or derived from natural brines, and including brucite but not including magnesite or dolomite or their derivatives, amounted to 369,257 short tons in 1942, valued at $10,727,560. The figures (137,357 tons valued at $3,587,784) given for 1941 in Minerals Yearbook, 1941, are not strictly comparable with those for 1942, as they do not include the production of magnesia from sea-water bitterns.

Expansion in magnesium chloride production for reduction to magnesium metal was the chief feature of the magnesium salines industry in 1942. The Dow Magnesium Corporation produced magnesium hydroxide from sea water at its new Velasco (Tex.) plant, finished in 1942. The magnesium hydroxide is converted to chloride and electrolyzed to magnesium metal. The same process is used in the nearby Freeport (Tex.) plant of The Dow Chemical Co. At Midland, Mich., The Dow Chemical Co. recovered magnesium chloride from well brines for use in making metal.

The Arizona Chemical Co. extracted magnesium sulfate (calcined) from well brines at O'Donnell, Tex. The C. A. Kearney Co. pumped magnesium sulfate-bearing brines from Epso Lake near Tonasket, Wash., and crystallized Epsom salt from the liquors. The Morton Salt Co. precipitated magnesium carbonate from well brines at its Manistee (Mich.) plant. The Ozark Chemical Co., of Tulsa, Okla., drilled wells into a magnesium chloride deposit near Gail, Borden County, Tex., and investigated methods of recovering commercial products from the brine.

Research into the extraction of magnesium salts from readily available magnesium silicate rocks continued in 1942. Olivine Products, Inc., Sylva, N. C., for several years a producer of Epsom salt from olivine and sulfuric acid, was inactive during the year, but the International Minerals & Chemical Corporation erected a plant at Augusta, Ga., to recover Epsom salt from serpentine. According to reports received by the Bureau of Mines, production was to begin early in 1943.

The Bureau of Mines, cooperating with the Geological Survey as agents for the Defense Plant Corporation, core-drilled into magnesium-bearing strata on the lease of the Utah Magnesium Corporation near Thompson, Grand County, Utah, in 1942.[15] A very rich section of carnallite ($KMgCl_3.6H_2O$) and sylvite (KCl), 220 feet thick, was cored at a depth of about 3,500 feet—the only magnesium-bearing section in the well. The lateral extent of the deposit is unknown, but it was estimated that the well cores prove 20 acres, with possibilities of a much larger area.

Part II.—MISCELLANEOUS SALINES

CALCIUM CHLORIDE

Shipments of calcium chloride and calcium-magnesium chloride from natural sources were 35 percent greater in quantity in 1942 than in 1941. However, total consumption of natural and synthetic calcium chloride is not believed to have increased significantly in 1942. The increased shipments of the natural material are said to have resulted from the shut-down of a former producer of synthetic calcium chloride. There were 13 producers of natural calcium and calcium-magnesium chlorides in 1942, compared with 10 in 1941.

Calcium chloride imported for consumption in and exported from the United States, 1938-42

Year	Imports		Exports	
	Short tons	Value	Short tons	Value
1938	1,642	$21,174	24,118	$396,981
1939	996	12,314	19,382	318,199
1940			8,907	194,738
1941	7	795	20,777	511,366
1942	1,443	18,926	8,336	223,184

Calcium chloride and calcium-magnesium chloride recovered from natural brines are largely byproducts of the manufacture of bromine, sodium chloride, magnesium chloride, and certain other salts. Most of the calcium chloride produced in the United States is a byproduct of soda ash manufactured by the ammonia-soda process, and its cost is borne by the soda ash; in this synthetic calcium chloride, the calcium comes from limestone and the chlorine from salt. The output is not canvassed by the Bureau of Mines, but it is estimated that 4,000,000 tons of synthetic calcium chloride in solution were available as a byproduct of the ammonia-soda process in 1942, of which it is estimated 175,000 tons (185,000 tons in 1941) were recovered and sold, competing directly with calcium chloride from natural brines. Producers estimate that approximately 90 percent of the total natural and synthetic calcium chloride available from all sources is thrown away.

The following firms reported production of calcium chloride and calcium-magnesium chloride from natural brines in 1942: California Rock Salt Co., 2436 Hunter Street, Los Angeles, Calif., plant at Amboy, Calif.; J. Q. Dickinson & Co., Malden, W. Va.; The Dow Chemical Co., Midland, Mich.; Great Lakes Chemical Corporation, Filer City, Mich.; Hill Brothers Chemical Co., 2159 Bay Street, Los Angeles, Calif., plant at Amboy, Calif.; Liverpool Salt Co., Hartford, W. Va.; Michigan Chemical Corporation, St. Louis, Mich.; Mullet Island Salt Works, Niland, Calif.; Ohio River Salt Corporation, Mason W. Va.; Pomeroy Salt Corporation, Pomeroy, Ohio, plant at Minersville, Ohio; Rademaker Chemical Corporation, Eastlake, Mich.; and Westvaco Chlorine Products Corporation, 405 Lexington Avenue, New York, N. Y., plants at Chula Vista, Calif., and South Charleston, W. Va.

Calcium chloride is used chiefly in road stabilization, which accounts for nearly half the consumption. It is used also in the treatment of coal, air conditioning, preventing evaporation and freezing of water in fire buckets, and as a desiccator in oil pipe lines. A new commercial use is in the recovery of lithium chloride from spodumene concentrates. The process, which was developed by the Bureau of Mines,[16] involves heating spodumene with calcium chloride at high

[16] Fraas, F., and Ralston, O. C., Chloride Volatilization of Lithium from Spodumene: Bureau of Mines Rept. of Investigations 3344, 1937, 11 pp.

Digitized by Google

temperature, whereby the lithium is volatilized as the chloride and recovered. Other important outlets for solid calcium chloride or its solutions are in freezeproofing coal and various ores, in removing ice on streets and highways, in brines at refrigerating plants, in curing concrete, and in calcium-soap lubricants. A comparatively new household use is in dehumidification of basements and cellars; kits for this purpose are available in many department stores.

Prices of calcium chloride, flake, 77 to 80 percent, carlots, delivered, ranged from $18.50 to $35.00 a ton throughout 1942, according to Oil, Paint and Drug Reporter. Solid calcium chloride, 73 to 75 percent, was quoted at $18.00 to $34.50 a ton, carlots, delivered; and 40-percent solutions, $7.50 a ton, tanks, works.

BROMINE

Shortage of gasoline for civilian use in 1942 was largely responsible for a 4-percent decrease from 1941 in output of bromine and its compounds, as bromine is a constituent of ethylene dibromide used in antiknock fluids. Nevertheless, heavy requirements for antiknock fluids for mechanized warfare maintained the total output of bromine at a relatively high level.

Bromine and bromine in compounds sold or used by producers in the United States, 1938–42

Year	Pounds	Value	Year	Pounds	Value
1938	33,324,116	$6,610,056	1941	68,317,019	$11,506,213
1939	37,882,005	7,611,400	1942	65,880,935	13,729,383
1940	59,266,275	11,772,515			

Fourteen plants produced bromine and its compounds in 1942, as follows: American Potash & Chemical Corporation, Trona, Calif.; J. Q. Dickinson & Co., Malden, W. Va.; The Dow Chemical Co., Midland, Mich.; Ethyl-Dow Chemical Co., Wilmington, N. C., and Freeport, Tex.; Great Lakes Chemical Corporation, Filer City, Mich.; Liverpool Salt Co., Hartford, W. Va.; Michigan Chemical Corporation, St. Louis, Mich.; Morton Salt Co., Manistee, Mich.; Pomeroy Salt Corporation, Minersville, Ohio; Rademaker Chemical Corporation, Eastlake, Mich.; and Westvaco Chlorine Products Corporation, South Charleston, W. Va., and Chula Vista and Newark, Calif. Most of it was produced by the Ethyl-Dow Chemical Co. at Wilmington, N. C., and Freeport, Tex., from raw sea water, and by The Dow Chemical Co. from well brines at Midland, Mich. Other raw materials used were sea-water bitterns and dry-lake brines.

An increasingly important use of bromine is in the preparation of methyl bromide, a fumigant for growing plants and stored grains. Bromine and bromides are also used in making tear gases, dyes, medicinals, photographic reagents, and certain kinds of synthetic rubber.

Digitized by Google

Most bromine enters the market as ethylene dibromide, which was quoted over a range of 65 to 70 cents a pound in 60-pound drums during 1942, f. o. b. plant. Sodium and potassium bromides, U. S. P., granular, were quoted at 27 to 31 cents in 500-pound barrels, works; ammonium bromide at 31 to 35 cents; and bottled elemental bromine in cases at 25 to 30 cents a pound.

IODINE*

There was no problem in iodine procurement in 1942, due to ample domestic production and to large stocks of Chilean iodine—estimated at a year's supply—held in the United States by the Chilean Nitrate Sales Corporation, New York City. Although some iodine was recovered on the West coast from kelp during the first World War, the American iodine industry really was born in 1928, when The Dow Chemical Co. undertook to recover iodine from oil-well waste waters near Shreveport, La. Dow later transferred its operations to Venice and Seal Beach, Calif., again using oil-well brines, and the Louisiana plant was shut down. The Deepwater Chemical Co., Ltd., Compton, Calif., also produces iodine from oil-well wastes. As there have been only two producers since 1937, the Bureau of Mines is not at liberty to reveal domestic output. In 1937, domestic producers shipped 299,286 pounds valued at $242,422. Production has been considerably higher in recent years.

Iodine is used in medicinals, photography, stock feed and human food, in organic syntheses, analytical reagents, leather manufacture, and special soaps.

American output is very effective in keeping the price of Chilean iodine low. As late as 1931, Chilean crude iodine sold in the United States at $4 a pound; in 1936 the price dropped to $0.90 but has gradually risen since then to $1.35 a pound less 5 percent, in 150-pound kegs, which price was constant throughout 1942. Resublimed iodine in 5-pound bottles, 50-pound lots, sold at $2 a pound during the year.

Imports of crude iodine, all from Chile, were 951,243 pounds valued at $1,051,432 in 1942, compared with 1,010,039 pounds valued at $1,121,513 in 1941. War Production Board General Import Order of December 17, 1942, prohibited import and export of iodine except by authorized persons.

Crude iodine imported for consumption in the United States, 1938–42

Year	Pounds	Value	Year	Pounds	Value

SODIUM SULFATES AND CARBONATES

Sales of natural sodium sulfates and carbonates increased 11 and 3 percent, respectively, in quantity in 1942 compared with 1941. Nine producers reported sales of natural sodium sulfate in 1942; eight reported for 1941. Natural sodium sulfate production rivals the output of salt cake and chemical sodium sulfates in the United States. Production of natural sodium carbonates, however, is small as compared with the quantity manufactured by the Solvay process, which yielded 3,944,000 short tons in 1942, according to Chemical and Metallurgical Engineering (vol. 50, No. 2, February 1943, p. 105). As in past years, nearly all the output of natural sodium carbonate was produced by four firms from Searles and Owens Lakes in California. In addition, a small quantity of soda ash was recovered from well brines in the vicinity of Green River, Wyo., which area is underlain by extensive strata of trona.[17]

It has been proposed for several years to recover potassium carbonate by reacting Green River trona with potassium-bearing wyomingite, also found near Green River, and in 1942 the Bureau of Mines erected a pilot plant to study the reaction.[18] Potassium carbonate is used in the glass, ceramics, and chemical industries.

Natural sodium sulfates and sodium carbonates sold or used by producers in the United States, 1935–42

Year	Sodium sulfates [1]		Sodium carbonates [2]

[1] 1935–38: Salt cake and Glauber's salt; 1939–42: Salt cake, Glauber's salt, and burkeite.
[2] 1935–41: Soda ash, bicarbonate, and trona; 1942: Soda ash and trona.

The American Potash & Chemical Corporation (plant at Trona, Calif., on Searles Lake) rushed the expansion of its Soda Products Plant during 1942; the new units were expected to be in operation early in 1943. As a raw material for some of its soda ash and salt cake, the expanded plant will use burkeite, a sodium carbonate-sulfate hitherto sold to the kraft-paper industry as a substitute for salt cake. The American Sulphates Co., Mecca, Calif., a new producer, extracted sodium sulfate from magnesium-sodium salts mined near Bertram, Imperial County, Calif. The deposit has been described by Sampson

[17] For a description of the deposit, see Smith, H. I., Trona in Wyoming: Am. Inst. Min. and Met. Eng. Tech. Pub. 1489, July 1942, 3 pp.

and Tucker.[19] The Arizona Chemical Co., 30 Rockefeller Plaza, New York City, increased its output of sodium sulfate from well brines near O'Donnell and Brownfield, Tex. The Desert Chemical Co., 4031 Goodwin Avenue, Los Angeles, Calif., extracted sodium sulfate and sodium chloride from well brines at its Dale Lake plant near Twentynine Palms, Calif. The company enlarged its facilities and drilled additional wells in 1942 with the intent of increasing its capacity to 50,000 tons of sodium sulfate and 80,000 tons of sodium chloride annually. The Iowa Soda Products Co., Council Bluffs, Iowa, mined sodium sulfate from an open pit near Rawlins, Wyo., and operated the Rawlins refinery at capacity during the year, producing Glauber's salt for mineral feed and veterinarian requirements. The Natural Soda Products Co., 405 Montgomery Street, San Francisco, recovered sodium carbonate at Keeler, Calif., from Owens Lake, Inyo County, for use mainly in glass, sodium chemicals, paper, and nonferrous metallurgy. The Ozark Chemical Co., Mid-Continent Building, Tulsa, Okla., operated its Monahans (Tex.) plant at full capacity during 1942, recovering sodium sulfate from well brines. The major portion of the output was of "salt-cake" grade and was shipped to kraft pulp mills; the remainder was consumed by the glass and chemical industries. The Pacific Alkali Co., 523 West Sixth Street, Los Angeles (plant at Bartlett, Calif.), extracted soda ash and trona from Owens Lake brines for use in mining and metallurgy, cleansers, and glass. W. E. Pratt, Casper, Wyo., mined sodium sulfate near Casper and converted it to Glauber's salt. The Washington Chemical & Salt Corporation, Brewster, Wash., in a test run extracted about 20 tons of sodium sulfate from a dry lake near Monse, Wash. The West End Chemical Co., 608 Latham Square Building, Oakland, Calif., increased its production of sodium carbonate from Searles Lake and began the construction of additions to its plant, including carbonating towers, tanks, and other facilities, the cost of which is estimated at $300,000.

The uses of natural and synthetic sodium sulfate are approximately the same; both are used in the manufacture of kraft pulp; flat, pressed, fiber, and optical glass; antimony recovery; stock feeds; dye standardization; and control of caustic embrittlement of boilers. The use of sodium sulfate in glassmaking was reviewed by Weyl.[20]

The chief use of natural sodium carbonates is in glass (mostly container), which takes nearly half the output. Large quantities of trona, $Na_2CO_3.NaHCO_3.2H_2O$, and hydrated sodium carbonate are consumed in cleansers. Increasing quantities of natural sodium carbonate are being used in the metallurgy of tungsten, molybdenum, vanadium, and antimony.

In 1942 the Bureau of Mines published a brief analysis of the production and uses of sodium carbonate.[21] The second edition of Manufacture of Soda, by T. P. Hou, was published by the Reinhold Publishing Corporation, New York City, in 1942.

Digitized by Google

Domestic salt cake was quoted at $15 a short ton, bulk, works; anhydrous sodium sulfate at $1.70 to $1.90 per hundredweight, works; and Glauber's salt at $1.05 to $1.28 per hundredweight throughout 1942, according to Oil, Paint and Drug Reporter. Soda ash, calcined sodium carbonate, was sold in 1942 at $0.90 to $3.25 a hundredweight, depending on grade and other factors.

BORATES

Boron-mineral production in 1942 slumped from lack of shipping space for exports and from shifts in the domestic consumption pattern. Shipments of boron minerals and boron derivatives made by the producers of boron minerals were 25 percent below those of 1941 in quantity. Five producers—all in California and same five that produced in 1941—reported shipments.

Salient statistics of the boron-mineral industry in the United States, 1938–42

	1938	1939	1940	1941	1942
Sold or used by producers: [1]

[3] Also 348 pounds of crude valued at $7 in 1939.
[4] Quantity sold or used by producers plus imports minus exports.

The American Potash & Chemical Corporation, 122 East Forty-second Street, New York City, extracted borax from the brines of Searles Lake at its Trona, Calif., plant and sold borax, dehydrated borax, and boric acid for domestic and foreign consumption in a wide variety of uses, but particularly in special glassware. The Pacific Alkali Co., 523 West Sixth Street, Los Angeles, recovered borax from Owens Lake, at Bartlett, Calif., chiefly for export. The Pacific Coast Borax Co., 510 West Sixth Street, Los Angeles, oldest and one of the largest producers, operated its kernite mines at Boron, Calif., and its Wilmington (Calif.) refinery (making kernite concentrates, borax, boric acid, and other boron derivatives) at near-capacity levels in 1942 for domestic and export trade. The United States Borax Co., 510 West Sixth Street, Los Angeles, mined colemanite (crude calcium borate) near Shoshone, Inyo County, Calif., for conversion into borax at a nearby refinery. The West End Chemical Co., 608 Latham Square Building, Oakland, Calif., recovered borax from Searles Lake at its Westend (Calif.) plant and sold both borax and dehydrated borax.

Digitized by Google

Before the war, borax was used chiefly in porcelain enameling. Owing to the lack of steel for making stoves, refrigerators, and similar articles, the amount of borax consumed in the enameling industry was small in 1942. The major wartime use is in glass, principally container and bottle glass, and kitchen utensils (replacing aluminum, stainless steel, and enamelware). Borax in the glass batch enables glass to withstand, with minimum breakage, such treatments as washing and pasteurizing; borax improves the tensile strength, elasticity, and hardness of glass, thus facilitating handling and shipping. The salt is used in many types of optical glass, in heat-resistant laboratory ware, in reflectors and beacons for airports, in water-gage glasses, in the bulbs of electron tubes, and in "foamglas" insulation.

Boron minerals and their derivatives are also used in the manufacture of pharmaceuticals, in water treatment (*p*H control), in making detergents, in textile treatment, in alloy steels,[22] as a preservative in adhesives, in rust inhibitors, and in abrasives. A molding sand for magnesium castings, containing boric acid to prevent reaction of magnesium with the moisture in the sand, has been described.[23] The use of borax in fire-retardant paints is discussed in Technical Notes 249 of the Forest Products Laboratory, Madison, Wis. Borax contents of 32 to 50 percent of the total paint are typical. A steel producer reported that kernite (crude $Na_2B_4O_7 \cdot 4H_2O$) could be substituted for aluminum as a scavenger in the ladle, on open-pour steels containing 0.10 percent carbon and under, accomplishing a saving of about 2.5 ounces of aluminum per ton of ingots without sacrificing quality.[24] The use of borax as a plant food is growing. Application of 10 to 20 pounds of borax per acre to boron-deficient soils is said to stimulate the growth of alfalfa, vetch, turnips, beets, and other plants. Many of the more important articles dealing with this use are reprinted in "Boron-O-Gram," a bimonthly published by the Pacific Coast Borax Co., 510 West Sixth Street, Los Angeles, Calif.

The price of technical borax, granular, bulk, works, remained at $41.50 a short ton throughout 1942, according to Engineering and Mining Journal Metal and Mineral Markets.

JEWELRY INDUSTRY IN 1942

Retail sales by jewelry stores in the United States totaled $699,000,000 in 1942—an all-time record and a 32.9 percent increase over 1941. Gains were particularly large in Washington and Oregon and in other areas where there are big war plants. As in the past 2 years, the increase was due to a large turn-over of relatively inexpensive items, although a few high-priced items were sold. Even the New York Fifth Avenue shops are showing more reasonably priced articles. The Christmas trade reached an all-time record, many believing it to be the last Christmas until the war is over when one could buy what one liked.

Increased sales were due to the marked rise in income of a large number of Americans (national income: 1939, 70 billion dollars; 1942, 119.8 billion dollars—thanks, unfortunately, to the war), to some investment buying, and to an all-time high in number of weddings (about 1,800,000 marriages, an 11-percent increase over 1941). Women war workers form a new class of jewelry-store customers, and some new fortunes are being made which will mean new purchasers of gems.

National income in 1943 will be even greater than that in 1942; and, notwithstanding the markedly higher taxes, the public will be ready to buy jewelry, particularly that moderately priced. Retailers will have difficulty in keeping their showcases filled, even though their business, as is likely, may average less than that of 1942. However, they can get diamond-set palladium jewelry and other gem stones, probably set in gold, and will find dealing in old jewelry profitable. As retailers face a shortage in help and higher operating costs and taxes, as well as ceiling prices on their wares, their 1943 profits are not likely to be as large as those of 1942.

Sales by wholesalers showed smaller gains (9 percent), and yet their stocks decreased (10 percent). Retailers' stocks decreased during the

Digitized by Google

year, and certain lines (watches, alarm clocks, etc.) were sold out during the Christmas season; they are begging wholesalers for goods, and of course, owing to Government regulations, the situation will become more acute. Late in 1942 the War Production Board limited the size of inventories that might be carried by the large and financially more stable companies in the hope that stocks might be distributed more evenly among retailers. Inventories in 1942 shrank only slightly.

As far as selective service is concerned, the jewelry trade is to receive few favors; jewelry artisans, lapidaries, and salesmen (both retail and wholesale) are nondeferrable.

Canadian retail sales were excellent before the new 25-percent excise tax was effective, June 23, 1942.

FASHIONS IN JEWELS

The rather severe modern gown requires the gaiety of jewels. Utilitarian, though smart, jewelry characterized the mode in 1942, and hence multiple-use clips and other double-duty jewelry were popular. The vogue for gold continued to grow at the expense of platinum, which cannot be used hereafter for jewelry. Regimental jewelry, "V for Victory," and floral designs were popular, although geometric, Hindu, and Latin American motifs also were used. Ensembles set with similar stones were much worn. Clips and brooches were especially popular; bracelets (identification and charm bracelets largely), earrings, and rings were also in demand.

Owing to the shortage of melee, pavé mountings are becoming rare. Topaz, amber, and aquamarine barbaric in size were used in bracelets and rings. Diamond (including some yellow stones), ruby, and sapphire (largely blue, but also yellow and pink) were the most popular gems, followed by topaz, aquamarine, amethyst, and amber. The insistent demand for diamonds and the patriotic motif in jewelry caused colorless stones to be dominant, followed by blue and red stones, then yellow and brown, and then green, purple, and black. The wide knowledge of gem stones, because of lectures by jewelers and courses in some colleges, is causing the American public to use a wider range of gem stones than ever before. Fine examples of certain of these stones are not too expensive, and some of them may be as beautiful as some of the noble gems.

DOMESTIC PRODUCTION

The production of gem stones in the United States in 1942 did not escape the blight of war, because producers sought minerals of greater strategic importance. Further, gas rationing in 1942 reduced not only collecting by amateurs but cut down the number of tourist customers who passed the lapidary's door. On the other hand, the shortage of foreign-cut stones improved the market for stones of American origin and cut. Intensified mining of pegmatitic ore bodies for block mica, beryl, and tantalite should have increased the production of aquamarine and other pegmatitic gem stones; but, if so, the miners appear to have high-graded the gem byproduct. Government-aided crystal mining (for radio plates) in Arkansas and California also probably increased the production of crystal suitable only for objets d'art. Makers of meerschaum pipes were short of the Turkish raw material, and satin spar was not available to the cutters of beads at Niagara

Digitized by Google

Falls. Restrictions on the use of silver in jewelry are said to have reduced the manufacture of turquoise-set jewelry by the Navajos.

It is believed that the net result of these various factors was a markedly smaller production of gem stones in 1942. A rough estimate of the value of uncut stones used in jewelry and related industries is $150,000 with a total value after cutting of $400,000; corresponding estimates in 1941 were, respectively, $240,000 and $770,000. Of the total value in 1942, sapphires (largely used industrially) represented 31 percent, turquoise 21 percent, and the quartz minerals 20 percent. The chief producing States in approximate order of output were Montana, Nevada, Oregon, and Wyoming.

Two corporations in Montana in 1942 produced sapphires weighing about 50,000 ounces (1.71 short tons) worth $47,000; most of these stones were stock-piled for possible use as instrument jewels, although a few were cut for gems. American Gem Mines (Charles H. Carpp, manager) at Philipsburg was the principal producer; this company sold its product to the Government. The Perry-Schroeder Mining Co., a gold-dredging company operating near Helena, was permitted, after the orders closing gold mines were issued, to continue dredging because of its sapphire byproduct. The New Mine Sapphire Co. at Utica and the Simon property near Butte did not operate.

The Smith mine near Beowawe, Nev. (product sold in California), was the principal turquoise producer; it yielded 13,033 pounds valued at $32,000. B. F. Couch reports that other Nevada turquoise miners produced about 350 pounds worth $4,000. The King property, at Manassa, Colo., also produced considerable turquoise, and a small quantity is said to have been mined near Kingman, Ariz. The Los Cerrillos mine, near Santa Fe, N. Mex., was not operated.

Dr. H. C. Dake reports that in 1942 gem mining in the Pacific Northwest (Washington, Oregon, Idaho, Montana, and Wyoming) was only about half as active as in 1941, although cutting of agate cabochons increased. Part of the lapidary industry was converted to the cutting of radio quartz plates. Fine moss agate was discovered about 8 miles southeast of Willowdale, central Oregon; the agate is reported to occur as a thick vein in rhyolite, and about 4,000 pounds worth $4,000 is said to have been mined.

Fine moss agates continue to be recovered from the gravels of Yellowstone River in southeastern Montana, but in diminishing quantities. R. L. Harris, of Miles City, Mont., a jeweler and moss-agate enthusiast, found on the banks of the Yellowstone a moss agate with a natural "V" for Victory on it. He had it cut and mounted in a ring of Montana silver and requested a national news weekly to present it to Winston Churchill; this was done, and the last leg of the journey was made in a ferry bomber. The Prime Minister was pleased to accept it. A little agatized wood, "rainbow" agate, and other forms of quartz are produced in Wyoming.

New occurrences of both green and black jade (nephrite) have been discovered in the general vicinity of Lander, Wyo. (personal communications of Fred Abernathy, Lloyd B. Curtis, H. C. Dake, and O. W. Plaga). Some of the green is of fine quality and worth $5 a pound. Boulders of jade, one of which is said to weigh almost 2,000 pounds, occur in an area 20 miles long and 3 miles wide paralleling Sweetwater River. Black nephrite is reported to occur in place in granite, but

Digitized by Google

the lighter green is known only as boulders. It is by no means impossible that after the war American jade will be exported to China.

A. M. Buranek reports that several hundred pounds of variscite were mined from the Clay Canyon deposit near Fairfield, Utah, and collectors obtained some variscite from Grantsville (Tooele County) and Lucin (Box Elder County). Fine agates and jaspers were obtained in eastern Utah. Considerable jet was collected from the Henry Mountains in southeastern Utah. Black obsidian with white christobalite inclusions, attractive when polished, has been found in Millard County, and some has been sold. Good topaz crystals were collected on Topaz Mountain, and pyrope garnet was obtained near Mexican Hat, San Juan County.

P. C. Leggett reports that several hundred carats of fine amethyst were produced in 1942 from two New Hampshire localities—Stark and Milan. The Stark locality, on Lone Mountain, is almost exhausted, but smoky quartz crystals occur rather abundantly in other "pockets" on the mountain. After heat treatment, the gem turns pale yellow. The Milan amethyst from Greens Ledge is not as fine as that from Stark, but the crystals are larger and less flawed. Gems of almost 30 carats have been obtained. Yellow, wine, blue, and colorless topazes also are found on Greens Ledge. Several good aquamarine crystals were found during the year in two mines in North Groton. Deeply colored, asteriated rose quartz was produced near the French mine in Gilsum.

Hugh D. Miser (see Bibliography) considers the veins from which the Hot Springs (Ark.) quartz crystals are obtained to be hydrothermal deposits of probable magmatic origin of mid-Pennsylvanian age. Although some of the finer crystals are sold for jewelry under the trade name "Hot Springs diamonds," most are sold to collectors or to constructors of water fountains and religious and memorial shrines. He estimates the value of crystals sold in 1941 at $12,000. Some are cut into radio oscillators. Crystals weigh from a small fraction of an ounce to 330 pounds. Certain localities furnish beautiful crystals of smoky quartz.

Other gems produced in the United States in 1942 included alabaster (South Dakota); albite (Maine); amazonstone (near Bar Harbor, Maine); amethyst (Maine); aquamarine (Amelia, Va.; Avon, Idaho); asteriated quartz (Wyoming); caesium beryl (Maine); lepidolite (Maine); moss agate (Siskiyou and San Bernardino Counties, Calif.); pipestone (Minnesota); rock crystal (Arkansas); rose quartz (Maine and South Dakota); greenish spodumene (Maine); topaz (Maine); tourmaline (Maine); and californite, a variety of vesuvianite, (Siskiyou County, Calif.).

CANADA GEM STONES

Dr. A. L. Parsons reports that a little rock crystal was discovered in 1942 in Leeds County, Ontario; otherwise, the industry, never important, was dead.

The Royal Ontario Museum at Toronto has a fine collection of Canadian gem and decorative stones, notably agate (Bay of Fundy and Thunder Bay district, Ontario); amethyst (Nova Scotia and Thunder Bay district, Ontario); and rose quartz (Lyndock Township, Ontario, and Manitoba). The rose quartz is deep in color and has

Digitized by Google

been used commercially to some extent. Included, also, are peristerite, an iridescent feldspar (Monteagle Township, Ontario); sodalite (Bancroft, Ontario, and Ice River, British Columbia); aquamarine (rare, Lyndock Township, Ontario, and southeastern Manitoba); golden beryl (rare, Manitoba); yellow scapolite (Grenville Township, Quebec); and amber (Cedar Lake, Manitoba).

IMPORTS[1]

Imports of precious and semiprecious (real and imitation) stones (exclusive of industrial diamonds) totaled $28,449,422 in 1942, a 16-percent decrease from 1941. Details are as follows:

Precious and semiprecious stones (exclusive of industrial diamonds) imported for consumption in the United States, 1941–42

Commodity	1941		1942	
	Carats	Value	Carats	Value
Diamonds:				
Rough or uncut (suitable for cutting into gem stones), duty-free	215,026	$10,301,371	277,826	$11,518,085
Cut but unset, suitable for jewelry, dutiable	229,582	18,346,415	125,806	14,599,770
Emeralds:

METAL SHORTAGES IN AMERICAN JEWELRY TRADE

Most of the common metals normally utilized in costume jewelry were diverted to national defense in 1941; and in 1942 use of most of the other metals in jewelry was prohibited. Limited amounts of domestic silver are still available, as, of course, is gold. Small amounts of the copper necessary to harden these metals can be used until June 30, 1943. The use of platinum, iridium, and rhodium in jewelry is forbidden. However, palladium alloyed with ruthenium is an acceptable substitute for platinum. Incidentally, should the need for it arise, the diamond-set platinum jewelry of United States citizens constitutes a considerable reserve of two critical materials for war purposes—platinum and diamonds. The Canadian manufacturer of jewelry is restricted even further, because the use of palladium is forbidden.

PRICE CEILINGS

Jewelry prices were frozen in June 1942 to the level effective during March 1942, although this did not affect "precious stones" as defined

[1] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Departments, Commerce.

Digitized by Google

by the Office of Price Administration. A precious stone, according to the OPA, is "any ruby, sapphire, emerald, natural pearl or any diamond weighing more than 1 carat or any semiprecious stone, after sale by the cutter, when the cutter has received more than $100 for sale of the stone." In addition, when "two or more diamonds with an aggregate weight of 1.5 carats are set in one mounting," the diamonds shall be deemed precious. According to this definition a faded ruby, a watery sapphire, or a badly flawed emerald weighing a carat is precious, but a half-carat, flawless, well-cut diamond is not.

CONVERSION OF THE JEWELRY INDUSTRY

The jewelry industry—as it produces in part articles of no value to the war effort and as it has been shorn of many of its raw materials—has been converted to war work to the greatest possible extent. Some of the larger units are wholly converted, the smaller less completely so, although some of the smaller shops, by pooling, have obtained valuable subcontracts. Silverware plants are making munitions; a firm formerly manufacturing expensive jewelry is now cutting quartz plates for radio work; and watch factories are turning out instrument jewels.

GOVERNMENT REGULATIONS

Every government, from the smallest to the largest, since the war began has had to formulate a host of regulations for the jewelry trade. The principal objects were to divert funds normally spent on jewelry to government securities, to discourage exportation of easily converted wealth, and to prevent critical material and needed skilled labor from being used to produce unessential merchandise.

EFFECT OF WAR ON THE GEM-STONE TRADE

In 1942, the United Nations lost Burma and thereby an important source of ruby, sapphire, spinel, jade, and tourmaline. On the other hand, when Dakar sided with the Fighting French, the Axis Powers lost the most important source of industrial diamonds remaining to them.

There is no shortage of gem diamond, ruby, emerald, and sapphire in America, nor of most of the less expensive precious stones, with the possible exception of zircon. The "good-neighbor policy" is making Americans more familiar with the lovely tourmaline, aquamarine, and topaz of South America. The lapidaries of the Northwestern States are cutting many agate and jasper cabochons for mountings of inexpensive jewelry. Supplies of synthetic stones and imitations are inadequate.

Owing to the war, Indian and Ceylonese stones (especially sapphire and star sapphire) arrive in New York direct instead of via Paris and London, as formerly. By air mail, elapsed time is 3 or 4 weeks.

Nazi puppets in the Netherlands, Croatia, and other dependencies continue to rob Jews of their jewelry, in instances having the effrontery to pretend that the funds which the jewels represent will be administered in favor of the victims.

Americans in India are buying jewels for souvenirs on an extensive scale. Jaipur, the principal Indian cutting center, has never been busier. As the business ethics of the average Hindu jeweler are low,

Digitized by Google

some American soldiers will find themselves possessing fine bits of glass; others will acquire jewels that will serve as heirlooms for generations to come. Algerian goldsmiths look upon the arrival of Americans as a reasonable excuse to quadruple prices.

DIAMOND

The diamond industry had its most prosperous year in over a decade, owing to unprecedented sales of industrial diamonds. Rough, suitable for gem cutting, also was sold in considerable quantity.

Production continued in 1942 at about the 1941 rate, although it was only 69 percent of that in 1940. A large part of the product of the mines of central and northwest central Africa—only African mines now operating—is of industrial grades, but the gem stones recovered are sufficiently valuable to keep industrial prices reasonable. Prices of rough and fine large cut continued to advance; those of small cut declined somewhat. In fear of inflation, "investment" buying increased in the black markets of Europe and the free market here.

Share dealings.—The shares of diamond-mining companies, virtually all of which are listed on the London Stock Exchange, gained over one-third in value in 1942. Their record was much better than that of the British industrials or American stocks in general. Frequently they were market leaders.

Stocks were hesitant for the first quarter, then advanced sharply; fell, owing to the British set-back in Libya, but from mid-July to the year end gained markedly. At the close of the year stocks stood at 560 percent of the all-time low (1932) and at 52 percent of the all-time high (1927). Nearly all the companies paid dividends in 1942, several at increased rates.

Market.—In 1942, the Diamond Trading Co., which in normal times controls the sale of about 95 percent of the world output, sold rough to the value of well over £10,500,000. "American qualities" (large fine rough) and fine small goods enjoyed a satisfactory market, but probably over 40 percent of the sales were of industrials. In mid 1942 the British Government appointed C. H. Rodwell diamond controller. The Trading Co. branch office at Hamilton, Bermuda, is said to have been closed recently, all stocks on hand having been sold.

In 1942 America bought large quantities of medium-size cut, particularly in the second half of the year. The other warring nations bought what they could, usually in "black" markets at fantastic prices. In time of war diamonds are natural "investments" to the enslaved people of a conquered country and to citizens of a belligerent country whose war future is dismal.

Prices of rough diamonds early in the year advanced 5 to 20 percent, according to qualities. Fine cut advanced 10 to 15 percent; melee slumped 30 percent in the first half of the year but rallied and was off but 10 percent at the year end.

Stocks of rough decreased markedly in 1942, as consumption exceeded production. Stocks in the hands of American cutters are probably adequate, as are those of fine large cut; the supply of small cut is abnormally low.

Imports.—As the following table shows, 1942 imports of gem diamonds were 91 percent of those of 1941, a small gain in rough imported being offset by a larger loss in cut. The quality of cut imported was excellent; that of rough was mediocre.

[1] United Kingdom of Great Britain and Northern Ireland.

Cutting.—In 1942 diamond cutting ceased its recent rapid growth, due partly to a slightly smaller demand for large cut but mostly to the diversion of artisans from gem to industrial cutting.

Now that the Low Countries are no longer factors in the cutting industry, the United States (750 cutters and 750 apprentices) and Palestine (reported as 2,500 cutters) are the largest cutting centers, followed by South Africa (400 cutters), Great Britain (300), Puerto Rico (75), and Cuba (66). Java, Borneo, and Brazil cut some diamonds for their local trade, but the cutting is not done well enough to satisfy the American trade.

Several of the belligerents propose to train their wounded as cutters, notwithstanding the unfortunate outcome of similar experiments after the First World War.

World production.—For the third year, due to the war, accurate diamond-production statistics are not available, but the estimates in

Digitized by Google

the following table are believed to be fairly accurate. World production (gems and industrials) in 1942 is estimated to have been 9,254,200 carats (1.851 metric tons) valued at $28,000,000. Compared with 1941, the weight increased somewhat more than 1 percent, and the value did not change. The quality was similar to that of 1941, bort representing about 79 percent of the total and gem stones 21 percent. Belgian Congo was the leading producing country, both in weight (65 percent of the total) and in value (29 percent). The British Empire produced 22 percent of the total by weight and 33 percent by value. As the South African pipe mines were not operated, all production was from alluvial mines.

The following table shows, as accurately as available statistics permit, world production for the past 5 years.

World production of diamonds, 1938–42, by countries, in metric carats

[Including industrial diamonds]

Country	1938	1939	1940	1941	1942
Africa:

Other countries [4]	34,200	19,000	31,750	34,350	44,350
Grand total	11,619,971	12,500,553	13,012,525	9,104,978	9,254,200

[1] Estimated.
[2] 1938–40: Exports; 1941–42: Production.
[3] South African production without Namaqualand was about 76,505 carats.
[4] 1938: U. S. S. R., India, Borneo, New South Wales, and Venezuela; 1939: Venezuela, India, Borneo, New South Wales, and U. S. S. R.; 1940 and 1941: Borneo, India, New South Wales, U. S. S. R., and Venezuela (Venezuela produced 29,399 carats); 1942: Borneo, India, New South Wales, Rhodesia, U. S. S. R., and Venezuela (Venezuela produced 34,084 carats).

Both Angola and Belgian Congo showed slightly greater production; but the decrease in South Africa was rather marked, indicating near exhaustion of its alluvial diggings.

In 1942 some of the companies attempted to increase production of the industrial stones so necessary today and succeeded in a small way. If the war continues, however, the long-term outlook is for a drying up of production, as certain essential supplies will be lacking owing to the isolation of the mines now producing.

Industrial diamonds.—In these days industrial diamonds steal the limelight from the gem variety, not only as to sales but as to romance. Concerning the latter, we may cite the recovery of several shipments snatched by the Allies from under the eyes of the Axis Powers.

The use of industrial diamonds, particularly of crushing bort, continues to increase beyond the expectations of anyone in the industry. Part of this expansion, of course, is due to the war program; but after the war is over, industrial diamonds will retain much of their gain in use. Consumption greatly exceeds production. The

Digitized by Google

finer grades continue to be scarce, but users are schooling themselves to utilize advantageously the grades that are available.

Germany and Italy are already feeling a shortage of industrial diamonds. Germany's shortage is dramatically indicated by the fantastic prices charged in the Swiss "black" market. Japan is in an even less enviable position, as it has not a store of gem stones to which it can resort.

Wholesale prices of industrials in 1942 remained firm; retail prices strengthened. During the year the War Production Board tightened its regulations as to transactions in industrial diamonds.

In pre-war days the percentages, by value, of the chief uses for industrial diamonds were as follows:

	Percent
Diamond drilling	45–40
Diamond-set tools	30–35
Diamond dies	10– 7
Crushing bort (bonded wheels and tools)	10– 7
Miscellaneous	5–11

Today the use of crushing bort is much greater, and the use of diamond-set tools and of dies is relatively greater, largely at the expense of diamond consumption in drilling.

Imports of industrial diamonds into the United States during the past 5 years were as follows:

Industrial diamonds (glaziers', engravers', and miners') imported into the United States, 1938–42

Year	Carats	Value		Year	Carats	Value	
		Total	Average			Total	Average
1938	1,396,247	$4,213,412	$3.02	1941	6,882,248	$14,908,809	$2.17
1939	3,568,730	9,725,683	2.73	1942	11,203,704	22,154,076	1.98
1940	3,809,071	11,026,563	2.89				

RUBY, SAPPHIRE, EMERALD

In Indian Precious Stones, by L. A. N. Iyer (Bull. 6, Records of the Geological Survey of India, Calcutta, New Delhi, 1942, pp. 17–23), the Indian sapphire localities of Afghanistan, Burma, and Ceylon are described. In its 40-year life (1885–1925), the average annual gross of the Burma Ruby Mines Co. was only about $300,000, sufficient reason why the company expired some years ago. The local natives carry on mining in a crude way, either by shallow shafts from which the "byon" is removed and robbed laterally as far as safety permits; by terracing the sides of a hill, somewhat after the Colombian mining practice; or by collecting gravels from limestone caves. The gravels are treated in an open, slightly sloping pond, in which the valuable gems sink and the valueless sands are washed away.

Edward Gübelin (see Bibliography) described the rather distinctly differing microscopic and other characteristics of sapphires from the major fields (Kashmir, Burma, Thailand, and Ceylon).

Digitized by Google

LESSER GEMS

Jade (nephrite) occurs in Burma in place in a dike, in a Tertiary conglomerate derived from it, and in modern stream gravels (Indian Precious Stones, by L. A. N. Iyer, pp. 38–41). Mining is confined to the dry months, March to May. Although the finer cutting is done in China (75 percent of the product is exported to that country), some stones are cut in Mandalay. The market depends on the prosperity of China; hence, at present it is depressed.

In 1940, Madagascar produced 4,400 pounds of agate, 1,004 pounds of rock crystal, and 28,508 troy ounces of precious stones of various classes. Its beryl, amethyst, and particularly its amber are fine.

Brazil is rich in precious stones. Its diamond and quartz crystal are mentioned elsewhere; one report states that in the first 9 months of 1941 Brazil exported the following additional gem stones to the United States:

Kind		*Quantity*	*Value, milreis*
Aquamarine	grams	26, 080	1, 912, 092
Amethyst	do	45, 286	666, 336
Tourmaline	do	3, 412	238, 027
Topaz	do	16, 561	175, 821
Agate	kilos	5, 410	83, 076
Other gem stones	grams	371, 129	1, 431, 107

About 63 percent of these exports reached the United States. Total exports of aquamarine in 1940 were reported to have been 1,169,034 grams, worth about $667,000, and in 1941, 524,651 grams, worth about $550,000. Brazil's cutting industry employs about 2,500 artisans.

An aquamarine weighing 109 kilos was found early in the summer of 1942 at Ariranho in the State of Minas Gerais. The owners were at once offered 800 contos for the stone, or about $40,000. A short time before, a fine block of rock crystal weighing 480 kilos had been found in the same region.

South-West Africa formerly sold its precious stones to the Germans; in consequence, since the war began very little if any mining has been done. In 1939, however, 4,075,031 grams of precious stones were produced, and 9,226,269 grams, worth £1,132, were exported to Germany. The principal stones were aquamarine, heliodor (golden yellow beryl), tourmaline (blue, through green, to a pale yellow-green), rose quartz, and chalcedony. A few colorless or light-blue topazes are also produced around Leideritz Bay in the diamondiferous gravels, and some agate. Apparently, so far as aquamarine, tourmaline, and topaz are concerned, the pegmatite druses at the surface are more or less exhausted. The unweathered rock is hard, requiring the use of dynamite in mining, and any gem stones recovered from such rock are likely to be flawed.

INSTRUMENT AND CHRONOMETER JEWELS

Before the war, the United States imported virtually all its instrument and watch jewels from Europe, particularly from Switzerland. Without such jewel bearings, high-grade instruments and chronometers to guide our aviators and to assist our bombardiers and Navy officers cannot be made. When war came, plants were created in this country to produce synthetic sapphire, and stocks of Montana sapphire were set aside as a reserve. Simultaneously, mechanical means of

Digitized by Google

fabrication were introduced. The program is apparently approaching successful completion. In addition, certain hard-glass bearings are being made, which will alleviate the situation. Imports for consumption of jewels for any movement, mechanism, device, or instrument or for any meter or compass numbered 92,547,236, valued at $2,007,012, in 1941 and 36,649,359, valued at $1,015,788, in 1942. In November 1942 the use of instrument jewels was confined to essential war work (WPB. M–50, amended Nov. 2, effective Nov. 2, 1942).

GENERAL CONDITIONS

Nitrogen, in various compounds, is an essential element in the domestic economy of the United States. About 500,000 short tons were consumed in this country yearly in normal pre-war times—nearly 400,000 tons in agriculture and the remainder in industry. The current war increased the domestic need for nitrogen for both agricultural and industrial purposes far beyond productive capacity or importation possibilities available at its start. The result was a shortage in nitrogen. In the recent past the demand for this element was met largely from domestic sources, but an important part of the supply has necessarily come from foreign countries, as the United States in the past was never self-sufficient in nitrogen supply.[2]

The war cut off some imports, hindered the importation of other commodities, and seriously disturbed the domestic nitrogen economy. Munitions factories had first call on the lessened nitrogen supply, and the military demands for nitrogen were so great that there was not enough for agricultural needs. Restrictions were placed on the use of nitrogen in fertilizers, and one after another of the nitrogen compounds was placed under allocation. Consumption in 1942 was exceedingly heavy, and the supply did not equal the demand either for munitions or agricultural use. Agriculture attempted to turn to organic nitrogenous materials for fertilizer use, and new synthetic nitrogen plants were started to satisfy the demand for explosives. On January 1, 1943, there had been built or were in process of construction in the United States synthetic and byproduct nitrogen plants with the huge capacity of at least 1,725,000 tons of nitrogen, a quantity nearly three times as great as the maximum pre-war consumption of nitrogen for all purposes. Development of this great productive capacity will release the United States from dependence upon foreign countries for supplies of this vital material, but it will introduce a hazard in the post-war economy because it exceeds any peacetime requirements that can now be foreseen.

INORGANIC NITROGEN COMPOUNDS

NATURAL NITRATES

Domestic nitrate deposits.—Deposits of soluble nitrate minerals are widely distributed in small quantities in the United States. Nitrate deposits have been found in 23 States, including the humid States Pennsylvania, Tennessee, and Alabama, but occurrences are much more numerous in the arid and semiarid parts of the West. Three types of nitrate deposits are known—cave, caliche, and playa. The cave nitrates are most widely distributed; the caliche and playa types occur only in the arid regions. The cave deposits contain the widest variety of nitrate salts, including potassium, sodium, calcium, and (more rarely) magnesium and ammonium nitrate. The caliche and playa deposits are chiefly sodium nitrate. The deposits are discussed in detail in various Geological Survey reports.[3]

The known natural nitrate deposits in the United States are too small and too low-grade to serve as a basis for a domestic nitrate industry. Furthermore, the general conditions under which nitrates occur in nature are quite well known, and this knowledge affords little hope that deposits of commercial size or quality will ever be found.

The United States has no domestic production of natural nitrates, so far as known. Cave nitrates were used occasionally in the past. The domestic caliche and playa nitrate deposits have never been worked.

Chilean nitrates.—Natural sodium nitrate and smaller quantities of potassium-sodium nitrate are imported from Chile. All Chilean nitrate of soda imported from July 1, 1942, to the end of the year was for the account of the Defense Supplies Corporation, a subsidiary of the Reconstruction Finance Corporation.

Sodium nitrate imported into the United States, 1938–42

Year	Chile		Total		Year	Chile		Total

remaining 20 percent for industrial uses. Control of allocation is under General Preference Order M–62 of January 15, 1942, effective February 1, 1942.

A stock pile of Chilean nitrate was started in Chile in 1941 by the United States Government.

SYNTHETIC NITROGEN COMPOUNDS

General.—The general situation with respect to chemical nitrogen up to the entrance of the United States into World War II is well-covered by recent publications.[4]

The following summary presents the major developments in the leading chemical nitrogen products in 1942.

Ammonia and its compounds.—In the United States ammonia (NH_3) is made principally by the high-temperature reaction of pure nitrogen and hydrogen under pressure in the presence of a catalyst. A relatively smaller quantity is recovered as a byproduct of the coking of coal. Ammonia is now used principally in military explosives, and, to a slightly smaller extent, in the manufacture of nitrogenous fertilizers. Smaller quantities are used in industrial explosives, chemicals, and in various minor ways. Agricultural consumption in 1941 has been estimated at about 65,200 short tons of nitrogen in the form of anhydrous ammonia and ammonia liquors; consumption in 1942 is believed to have decreased because during part of the year the use of these commodities for the direct ammoniation of superphosphate was prohibited.

Although the production of synthetic ammonia at privately owned and Government plants made an all-time record in 1942, the supply was still short because of the greatly increased demand for its use in making munitions and in other war industries.

The United States capacity for the production of synthetic ammonia is being vastly increased. Several new plants have been erected, and others are in process of erection. It is reported that eventually there will be synthetic-ammonia plants in 10 or more States.

General Preference Orders M–163 and M–164, effective June 1, 1942, placed both byproduct ammonia and synthetic ammonia under complete allocation by the War Production Board. There was no Government stock piling in 1942.

Ammonium sulfate is one of the most important agricultural fertilizers and one of the principal sources of nitrogen in mixed fertilizers. Production increased in 1942 over 1941, but sales declined from 756,569 short tons in 1941 to 751,914 tons in 1942. In 1941, agricultural consumption of this commodity in the United States totaled 138,248 short tons of contained nitrogen, or 30.6 percent of the total nitrogen consumed in agriculture.[5]

Byproduct ammonium sulfate was placed under allocation by the War Production Board in General Preference Order M–163 of May 30, 1942, effective June 1, 1942. Allocation did not change the use pattern, and most of the ammonium sulfate is stated by the War

Digitized by Google

Production Board to have gone to the fertilizer industry, but smaller quantities were allocated than before.

Ammonium nitrate, hitherto used chiefly in the manufacture of explosives, is being utilized to a considerable extent as a nitrogenous fertilizer. Tennessee Valley Authority Nitrate Plant No. 2 at Muscle Shoals, Ala., was modernized and rehabilitated in 1942 and began to produce and ship ammonia nitrate for explosives and later for fertilizers. Imports of a mixture of ammonium nitrate and limestone, produced in Ontario, Canada, were released by the War Production Board early in 1943 for direct application to the soil.

Sodium nitrate.—When the United States entered World War II, only one domestic establishment was producing synthetic sodium nitrate—the Hopewell (Va.) plant of the Allied Chemical & Dye Corporation. Several new domestic plants were erected and began operations in 1942. The production capacity of synthetic sodium nitrate plants in the United States at the end of 1942 has been estimated at about a million tons annually, but this capacity could be attained only at the expense of reducing supplies of ammonia available for other purposes. Most of the domestic synthetic nitrate of soda produced in 1942 is reported to have gone to munitions plants, and the remainder to fertilizer consumers. The allocation of synthetic nitrate of soda is covered by the same order (General Preference Order M-62) as is Chilean nitrate.

Cyanamid.—Imported Canadian calcium cyanamid, a synthetic fertilizer, has contributed materially to meeting United States needs. It has been produced since about 1910 at the plant of the American Cyanamid Co., of New York, at Niagara Falls, Canada. Domestic production has been limited to a single venture of the United States Government. Nitrate Plant No. 2 at Muscle Shoals, Ala., was originally erected as a cyanamid plant, but except for a 2-week trial run in 1919 it was never operated. Calcium cyanamid is, like other chemical nitrogen fertilizers, under allocation (Conservation Order M-231).

ORGANIC NITROGEN COMPOUNDS

Organic nitrogenous materials of vegetable or animal origin, such as tankage, fish scrap, cottonseed meal, castor pomace, dried blood, guano, bones, sewage sludge, and tobacco stems, are utilized entirely in the fertilizer and feed industries and compete with chemical nitrogen products. The best grades, however, contain an average of only 5 to 12 percent nitrogen. The demand for some of these materials for animal feed is increasing.

Restriction in the use of chemical nitrogen in fertilizers after September 1942 resulted in an increased demand for organic nitrogen compounds, and competitive bidding by feed makers and fertilizer interests led to shortages and unequal distribution.

CARBON DIOXIDE

Carbon dioxide, widely known as a means of supplying sparkle and palatability to carbonated beverages and in its solid form as a highly efficient refrigerant, has constantly increasing utility in war equipment. In this field it is used as a fire extinguisher in tanks, trucks, and airplanes and as an inflating agent for life preservers and rafts.

Production of commercial carbon dioxide in the last 6 months of 1942, as compiled by the Chemical Branch of the War Production Board, was 146,173 short tons of dry ice valued at $7,308,650 and 76,981 short tons of liquid and gas. The value of carbon dioxide in liquid or gaseous form ranges from 1 cent to 8 cents per pound, depending on the purity of the product; as the total for liquid and gas is given as one, no attempt has been made by the Bureau of Mines to compute an average or total value.

GRAPHITE

Demand for all qualities of graphite, except natural amorphous, was greater in 1942 than in 1941; demand for crucible-grade material was greatest. Aided by conservation orders and restrictions, stocks of both Madagascar flake and Ceylon lump were at higher levels than in 1941.

Graphite has been placed on the critical materials list, but only about 10 percent of the graphite employed in the United States has critical importance. This is principally flake graphite from Madagascar, used in crucibles. Although the advent of electric furnaces for manufacturing high-grade steel reduced the demand for graphite crucibles, fairly large numbers are still used in melting nonferrous metals and some steels. Flake graphite is used also in retorts for smelting and refining zinc and brass.

On December 28, 1941, graphite was included under General Imports Order M–63, which placed imports of critical materials under Govern-

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

Digitized by Google

ment control. On February 17, 1942, the War Production Board issued Order M–61, restricting the use of plus-35-mesh Madagascar flake graphite to the manufacture of crucibles, and named the Metals Reserve Co. as sole importer of graphite of this quality. On December 4, 1942, the order was amended to include all crystalline graphite (in flake, lump, or chip form) that will stand on a No. 50 mesh screen, U. S. Sieve Series. The United States depends principally on Madagascar and Ceylon for its supplies of strategic-grade graphite; therefore, imports in the following table are of primary importance.

Graphite (natural and artificial) imported into the United States for consumption, 1938–42

Year	Crystalline				Amorphous				Total (natural and artificial)	
	Flake		Lump, chip, or dust		Natural		Artificial

[1] Less than 1 ton.
[2] India and Dependencies (British India).
[3] United Kingdom of Great Britain and Northern Ireland.

The Madagascar total of 5,850 short tons represents shipments received in March and April 1942, the only months of that year during which graphite arrived from the island. As a result of the allocation order of the War Production Board and its subsequent revision, the existing industrial and Government stocks of crucible flake on hand at the end of the year were adequate for current needs plus a 9-month reserve (3,600 short tons). The supply of Ceylon lump material was in an even more favorable condition. Based on the quantity consumed during 1942 (800 short tons) and requirements estimated by the War Production Board for 1943 (900 short tons), the stock of 1,300 short tons at the end of 1942 represents a reserve of approximately 15 months' supply. Stocks of graphite fines represent a 2 years' supply.

Digitized by Google

Exports of natural graphite, 1938–42, were—1938: 983 short tons, valued at $112,443; 1939: 976 tons, $109,715; 1940: 1,632 tons, $148,639; 1941: 1,723 tons, $166,612; and 1942: 4,420 tons, $448,141.

Exports of natural graphite represent, for the most part, reexports of Madagascar flake; the export market includes U. S. S. R., England, Canada, Mexico, and several South American countries.

As foreign shipments are uncertain, efforts were continued to promote a larger domestic output. The Bureau of Mines continued its investigation of possible domestic sources. Graphite samples from Alabama, Georgia, Pennsylvania, New York, Texas, and California were collected and analyzed. Various flow sheets were used in an attempt to determine the best method of recovery with minimum degradation of the coarse flake. The data from these tests were used as a guide in designing plants to produce crucible-grade flake graphite approved by the War Production Board.

Five plants have been built with the assistance of loans from the Reconstruction Finance Corporation—three in Alabama and one each in Texas and Pennsylvania. They have a combined capacity of 4,300 short tons of crucible-grade graphite a year. Only one of the new plants was in operation during 1942, but all of them were producing by the end of the first quarter of 1943. The combined total of crystalline and amorphous graphite produced by domestic mines in 1942 was 7,070 short tons; except for part of the Ceylon Graphite Co. output, which sold as crucible flake, domestic graphite was used chiefly in foundry facings and paint. Artificial graphite was manufactured and sold by the Acheson Graphite Co., 30 East Forty-second Street, New York, N. Y., from a plant operated at Niagara Falls, N. Y.

The Canadian graphite industry is again becoming active as the result of a diamond-drill program by Ventures, Ltd., on the old Black Donald graphite property in eastern Ontario. Drilling has disclosed reserves of 40,000 tons of commercial-grade ore to a depth of 300 feet. The mill has been rehabilitated to treat 50 to 75 tons of ore daily.

Some impetus will be given to Mexican trade because of a trade treaty, signed December 23, 1942, which reduces the ad valorem duty on graphite from 10 percent to 5 percent. The treaty is effective for 3 years and thereafter until 6 months after either Government serves notice of termination.

Prices for Madagascar and Ceylon graphite in carlots, f. o. b. New York City, duty paid, in 1942 were as follows, in cents per pound: Madagascar, No. 1 Flake, 9 to 16; No. 2 Flake, 7; Fines (ground), 55 to 70 percent carbon, 3; Ceylon Lump, 10 to 12; Carbon Lump, 9 to 10; Chip, 7; and Dust, 4 to 5.

Figures for total world production of graphite are not available. A table covering the period 1915–39 appeared in Minerals Yearbook, Review of 1940 (p. 1414), and the following table includes all production figures from 1937 through 1942 that can be obtained.

KYANITE, ANDALUSITE, AND DUMORTIERITE

Production of the sillimanite-group minerals increased in 1942 but not enough to keep pace with demand. The supply situation was aggravated by curtailment of shipments from India, occasioned partly by the threat of Japanese invasion of that country during the early months of 1942 and partly by lack of shipping facilities.

Domestic production, imports, and stocks of kyanite in the United States, 1940–42

Year	Domestic production		Imports from British India		Total new supply		Stocks [1]	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

Imports of Indian kyanite were received every month of 1942 but July and August. Although the proposed 1,500-ton Government stock pile had not materialized, industry stocks were still a year ahead of the current requirement rate.

Domestic production of kyanite failed to attain expected proportions, chiefly because of dffiiculties in two eastern locations. Celo Mines, Inc., at Burnsville, N. C., pioneer producer in the east (which in 1941 became Mas-CeloMinnes, Inc., subsidiary of Munn & Steel of Newark, N. J.), ceased operation in June 1942; it was later reorganized as the Yancey Cyanite Co. and financed by the Reconstruction Finance Corporation. Mining and milling were resumed in February 1943 on a schedule of 12 tons of kyanite concentrate a day, or 300 tons a month. Half of this production will be low-iron glass-grade kyanite (Fe_2O_3 content, not over 0.20 percent) and the remainder refractory grade. This company will do no calcining.

The Kyanite Products Corporation near Farmville, Va.—largest individual domestic producer—hampered by bad weather during the last quarter of the year and by loss of employees to the armed forces produced several thousand tons less in 1942 than capacity output. With an enlarged plant and stabilization of manpower, increased production is expected during 1943.

Experimental work is still in progress to improve the grade of domestic kyanite, so that it may be used as a substitute for Indian kyanite. It makes an excellent mortar and may also be used in plastics, but at present it is not regarded as a satisfactory substitute in superrefractories for the Indian material.

The cost of Indian kyanite delivered at Atlantic seaports rose from a little over $30 per short ton in 1941 to $54 in 1942. Prices for domestic kyanite have been set by the Office of Price Administration under Order MPR 327 released February 17, 1943. On and after that date domestic kyanite cannot be sold, delivered, or bought at a price above the highest net charged by the operator for the same product on a delivery made during March 1942.

Under this order specific prices were set for the Yancey Cyanite Co. (Asheville, N. C.) at $22 per short ton f. o. b. plant for refractory-grade and $40 for glass-grade material. Prices set for the Kyanite Products Corporation (11 Broadway, New York, N. Y.) were $19 per short ton for raw kyanite, 35-mesh in carlots, to $37.50 for 325-mesh material, less than carlots in 100-pound bags; for calcined kyanite in 100-pound bags, the range was $26.50 per short ton, 35-mesh in carlots, to $42.50 for 325-mesh material, less than carlots, f. o. b. Cullen or Pamplin, Va.

Production of andalusite on White Mountain, Mono County, Calif., and dumortierite at Oreana, Pershing County, Nev., by Champion Sillimanite, Inc., Merced, Calif.—only domestic producer of either mineral in 1942—increased sharply over the 1941 total. This material was shipped to the parent firm—Champion Spark Plug Co., Detroit, Mich.—for use in spark-plug cores and other electrical porcelains.

Experimental work on sillimanite from a deposit near Troy, Latah County, Idaho, indicates that the crude material must be beneficiated by flotation or a similar process of concentration to be marketable.[2]

A large deposit of sillimanite in the Broken Hill district, New South

Wales, Australia, has been investigated by the Board of Economic Warfare through the War Supplies Procurement Mission of the Commonwealth of Australia. In January 1943 a 200-ton sample of this material was received in the United States by Charles F. Taylor & Sons Co., Cincinnati, Ohio, for use in experimental work in the manufacture of high-temperature refractories. If the tests are successful and shipping space is available a definite market can be developed for this material.

LITHIUM MINERALS

Shipments of lithium minerals and compounds reached 5,405 short tons valued at $243,516 in 1942 compared with 3,832 tons valued at $115,718 in 1941; they originated in four States—South Dakota, North Carolina, California, and Maine. Lithium used as a scavenger in metal refining and as an alloy, the stearate in greases, the chloride in air-conditioning industrial plants and in dehydrating air in blast furnaces, and the hydride as a transporter of hydrogen have increased in importance during the war. Available production facilities were inadequate to meet these increasing demands. On December 5, 1942, the War Production Board promulgated Order M–253, placing all lithium ores under control of the Director General for Operations. This order includes not only ore produced on that date and thereafter but also stocks held within the continental limits of the United States as of that date, whether in private or Government hands. A much more favorable supply situation will be created in 1943 by the completion of the new plant of the Solvay Process Co. at Kings Mountain, N. C., and the rebuilding of the Black Hills Tin Co. mill at Tinton, S. Dak. (destroyed by fire January 5, 1943), and the entrance of several new producers into this field.

Under supervision of the War Production Board all new plants set up to produce and concentrate lithium ores were constructed to mill spodumene because of its relative abundance and ease of separation. Production is also confined to extraction of the chloride, to the exclusion of other compounds which are used in ceramics.

The United States is the leading producer and consumer of lithium ores and compounds and apparently has the largest known ore reserves. South-West Africa, Australia, and Sweden produce the remainder of the world total, except for a small output from Canada, Portugal, Southern Rhodesia, Spain, and Germany.

Information on world production of lithium ores has been meager since 1937, when the United States produced 52 percent of the world total, South-West Africa 42.5 percent, Portugal 4 percent, and other countries 1.5 percent. In pre-war times Germany produced about the same amount of lithium compounds as the United States; however, these were derived largely from ores imported, chiefly from the United States and South-West Africa. The present German position is therefore unfavorable, as the only sources of imports available to Germany are Sweden, Spain, and Portugal, which are minor producers. Stocks are not known but are probably small or nonexistent, as this mineral is usually mined as needed.

Prices for lithium ores produced in the United States for sale on the open market, as quoted by Engineering and Mining Journal Metal and Mineral Markets, were constant during 1942 as follows: $5 per 20 pounds of contained lithia (Li_2O), 6 percent minimum, relatively free of iron, quartz, and tourmaline, $30 per short ton in carlots; amblyg-

Digitized by Google

onite, 8 to 9 percent Li_2O, $40 per short ton f. o. b. mine; and lepidolite, 3 percent (Li_2O), $24 to $25 per short ton f. o. b. mine.

MINERAL EARTH PIGMENTS AND MANUFACTURED IRON OXIDE PIGMENTS

[Prepared by Charles L. Harness]

World War II hastened domination of American markets by domestic pigments and encouraged local manufacture of many foreign-type pigments, thus accelerating trends in the earth-pigments industry that had been discernible for several years before 1939. Improvements in processing domestic pigments have offset without great difficulty the curtailment in imports of French yellow ochers, Spanish and Persian Gulf red iron oxides, Italian siennas, Turkish umbers, and German Vandyke and sap browns. Although the Bureau of Mines has no complete sales figures for mineral pigments in 1941 comparable with those for 1942, it estimates that total production was 30 percent greater in 1942 than in 1941.

Many producers geared their operations more closely to war needs in 1942. The Clinton Metallic Paint Co., Clinton, N. Y., formerly specializing in natural red iron oxide (Clinton hematite and blended colors based on it) for use in brick and mortar colors, installed equipment to prepare the pigments for paint use. To meet increased demands for earth pigments, the Geo. S. Mepham Corporation erected a new plant at East St. Louis, Ill. The Mineral Pigments Corporation, Muirkirk, Md., announced completion of new improved methods for synthesizing red iron oxides, Vandyke brown, and siennas; the siennas, which are made from scrap iron, are said to be considerably superior to Italian siennas. Reichard-Coulston, Inc., Bethlehem, Pa., built a plant for manufacturing synthetic yellow iron oxide for olive drab and camouflage paints. The Tamms Silica Co., Chicago, Ill., improved red iron oxides for use in rust-inhibiting primers and expanded its plant capacity for this and other products. C. K. Williams & Co., Easton, Pa., was active in camouflage-pigment research and was particularly successful in developing infrared-reflecting pigments.

Natural mineral pigments and manufactured iron oxide pigments sold by processors in the United States in 1942, by kinds

Pigment	Short tons	Value

[1] Less than ½ ton.

Prices of finished earth pigments, which are quoted in cents per pound, were generally unchanged during the year, according to Oil, Paint and Drug Reporter. Precipitated magnetic blacks, in barrels, less carlots, works, were quoted at 8.5; metallic browns declined from 2.6 to 2.35; and Vandyke brown sold at 9, sap brown crystals at 12, synthetic browns at 12, natural red iron oxides at 2, synthetic red iron oxides at 9, Venetian reds at 2.2 to 4 (depending on iron oxide content), and natural yellow oxides, high iron, at 5. Synthetic iron oxide yellows declined from 7.25 to 7.1 during the year as production increased; domestic French-type ochers declined from 3.65 to

Digitized by Google

3.45; burnt siennas were quoted over a range of 3.5 to 6 (depending on quality), the prices declining slightly toward the end of the year; raw siennas ranged from 3.25 to 10, depending on quality, the quotations rising later in the year; and umbers were quoted at 3.375. Raw, untreated earth pigments are purchased by processors over a wide range of prices, from less than $1 to as high as $10 a ton at the mine.

MINERAL WOOL

The necessity of saving fuel for military uses, increasing the efficiency of industrial plants, and maintaining temperatures at normal levels in homes with less fuel during the war has hastened realization of the true economy of insulation.

It is estimated that production of mineral wool in 1942 reached 500,000 short tons valued at $22,500,000,[3] representing production from 58 companies operating 70 plants. To meet the unusual demands, the industry operated virtually at capacity, and this capacity was enlarged substantially by improvement in melting technique, which increased the output of mineral wool per ton of fuel from 2 to 1 to about 4 to 1 as an average, with a maximum of 6 to 1 in several plants. Efforts are being made to stabilize employment in the industry by encouraging dealers to purchase on a monthly basis rather than seasonally and thus keep production and employment in constant balance.

Through the efforts of the National Bureau of Standards and the Industrial Mineral Wool Institute, commercial specifications for the use of mineral wool in loose, granulated, or felted form in low-temperature installations were established in December 1942, to be effective on and after March 1, 1943. Tests at the National Bureau of Standards in Washington, D. C., the Engineering Experiment Station of the University of Illinois, and the National Research Council of Canada, as described in a recent Bureau of Mines information circular,[4] show that complete insulation of homes results in a 30-percent saving in fuel consumption.

This fuel saving is particularly important to the eastern region, which contains 65 percent of the total oil burners installed in the United States. The Office of Price Administration estimates that 51 percent of the houses having oil burners are insulated.

Mineral-wool insulation has been specified for use in military equipment by the War and Navy Departments for tanks, airplanes, and bulkhead insulation in ships. The loss of life by fire and suffocation from fumes of burning-cork insulation in sinking ships during the Pearl Harbor attack was responsible in large measure for the change in specifications for ship insulation. Prices in 1942, per short ton in carlots, f. o. b. plant, were $30 for loose mineral wool and $45 for granulated wool.

MONAZITE

Monazite sand is the only commercial source of cerium, other rare-earth oxides, and thorium which, although used in rather small quantities, are essential to many industries. The United States

[3] Estimate by Bureau of Mines, based on figures obtained from War Production Board covering first half of 1942.

[4] Bowles, Oliver, Home Insulation with Mineral Products—Conservation of Fuel for War: Bureau of Mines Inf. Circ. 7220, 1942, 15 pp.

Digitized by Google

depends entirely upon British India and Brazil for its supplies. Imports of monazite sands in 1942 increased 950 short tons over 1941, and the tonnage received from Brazil represented 31 percent of the total in 1942 as against 21 percent in 1941. If need be, Brazilian production can be expanded to supply all our essential requirements. The stock pile of these sands—entirely in the hands of industry—is in excellent condition, containing 2½ years' supply at the current rate of consumption as of March 1943.

Monazite sand and other thorium ore imported into the United States for consumption, 1938–42, by countries of origin [1]

Country of origin	1938		1939		1940		1941		1942	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
Brazil	110	$3,421	54	$1,516	201	$7,440	734	$25,240	1,346	$62,555
India and Dependencies [2]	339	14,402	1,336	46,753	2,766	92,387	2,714	82,068	3,052	112,928
Netherlands Indies			170	3,747						
United Kingdom [3]	7	387								
	456	18,210	1,560	52,016	2,967	99,827	3,448	107,308	4,398	175,483

[1] Quantities are gross weight; monazite content not reported.
[2] British India.
[3] Great Britain and Northern Ireland.

Commercial utilization of the various elements in monazite sand has expanded considerably in the past few years. The original basis of value of 6 to 8 percent thoria content has been superseded by the ceria and other rare-earth oxides content, and requirements are now based on a 57- to 60-percent minimum of rare-earth oxides. Considerable technical skill is required to extract the rare-earth metals from these sands, and for many purposes the rare earths are used as a group. Cerium and the cerium group—the most important rare-earth elements—are used principally as arc stabilizers in carbon arc lamps, as mildew-proofing agents, and in the manufacture of pyrophoric alloys. Thorium is used principally in electron-emissive elements, praseodymium and neodymium are used in the manufacture of special optical glasses, and lanthanum and erbium in beauty preparations.

The market for these sands is variable and sporadic; therefore, buyers' specifications are elastic. Indian sands are finer-grained and have a higher thoria content than those of Brazil. The following quoted prices are nominal: $42.50 per long ton f. o. b. India plus $24 ocean freight to Baltimore; and $64 per metric ton f. o. b. Brazil plus $17 ocean freight to Baltimore.

OLIVINE

Shipments of olivine reached 5,739 short tons valued at $45,201 in 1942 and were consumed entirely in refractories. This tonnage is the largest ever produced and shipped in the United States. Olivine occurs in commercial quantities only in the rock dunite and in its alteration products, serpentine and steatite. These rocks, in lump or ground form, make up the material produced and sold as olivine.

Olivine deposits are found chiefly in Washington, California, North Carolina, and Georgia. A review of these deposits, which includes an estimate of their reserves and a description of their development in the

Digitized by Google

past few years, has recently been published.[5] Of particular interest is the experimental work now in progress to determine the potentialities of olivine as an ore of magnesium.

Prices for crude olivine, f. o. b. North Carolina, were quoted at $7 to $9 per short ton, and for ground olivine, 8- to 200-mesh, at $12 to $20 per short ton.

QUARTZ CRYSTAL

Piezoelectric-grade quartz crystals, which are required for radio oscillators and filters, telephone resonators, and other sound equipment, head the list of strategic and critical minerals published by the War Production Board. Although several domestic sources of supply bear some promise, we still depend upon Brazil for quartz of this grade, and the question as to whether our supply from Brazil will be adequate to meet the present requirement rate depends upon the extent to which small crystals can be used.

Imports of quartz pebbles reached 1,305 short tons valued at $8,941,965 in 1942. Except for imports of 1,024 pounds from Guatemala and 61 pounds from Colombia, which were sample shipments, the entire quantity was received from Brazil. This tonnage supplied 5,202,808 small [6] oscillators, 1,576,782 large [6] oscillators, 91,173 telephone resonators, and 17,050 units for detection equipment.

However, much of the quartz received did not meet specifications, and more thorough, systematic check of the material in Brazil was begun. American engineers were sent to visit the various producing areas, and inspection laboratories were set up in Rio de Janeiro. Toward the close of 1942 production increased, and quality improved.

On May 18, 1942, the War Production Board under Order M–146 assumed control over the products for which quartz crystals may be used; and on August 4, 1942, under General Imports Order M–63, importers were required to obtain War Production Board authorization for disposal of quartz crystals in this country. Beginning in January 1943 most of the crystals imported into the United States were air-borne, arriving at New York City, Washington, D. C., and Miami, Fla.; the largest portion entered at the Florida port. Only the low-grade material (of which about 10 percent will be usable) will be brought in by ships, and it will be purchased entirely by the Metals Reserve Co.

Arkansas, California, and certain other areas in the United States offer possibilities for developing domestic quartz-crystal production. The Hot Springs area in Arkansas offers two good possibilities, each of which (it is believed) will yield about 50 tons a year of 30-percent-usable material. Samples of Arkansas quartz when tested show a higher piezoelectric activity than Brazilian material.

Complete specifications and prices for piezoelectric-grade quartz have not been formulated, chiefly because of the lack of a systematic and consistent method of mining and grading the material at the source. The original specifications called for quartz, each piece weighing not less than 200 grams, 30 percent or more of which must

[5] Gwinn, G. Richards, Olivine: Bureau of Mines Inf. Circ. 7239, 1943, 11 pp.

[6] "Small" defined as one-half inch or smaller in January–April and October–December 1942; as five-eighths inch or smaller in May–September.
"Large" defined as sizes above these in same periods.

Digitized by Google

be free from inclusions, cracks, needles, bubbles, or twinning. Because of improved technique developed under the urge of necessity, smaller crystals were subsequently accepted. The minimum size has been reduced in several stages until in March 1943 it stood at 50 grams.

STRONTIUM MINERALS

[Prepared by Charles L. Harness]

Sales of celestite (crude strontium sulfate) by domestic producers declined somewhat, amounting to 4,041 short tons valued at $55,529 in 1942, compared with 4,724 tons valued at $69,054 in 1941. Despite an active market for use in tracer bullets and flares, no new deposits of chemical-grade celestite were worked commercially in 1942. Production of the abundant subchemical-grade celestite in Texas, formerly used entirely for oil-well drilling muds, declined with curtailment in drilling activity, although some of the higher-grade rock was sold for purifying caustic soda and for conversion to strontium chemicals, both with and without beneficiation. Research by the Bureau of Mines and by the Foote Mineral Co. on methods of beneficiating crude celestite found in Brown and Nolan Counties, Tex., indicated that the impure celestite can be beneficiated to a plus-92-percent content of strontium sulfate.

Imports of celestite into the United States amounted to 10,387 short tons valued at $144,848 in 1942, mostly from Mexico, compared with 4,294 tons valued at $66,271 in 1941, mostly from the United Kingdom.

Prices for chemical-grade celestite, lump, ranged from $30 to $35 a short ton laid down in the Philadelphia area.

TOPAZ

The United Feldspar & Minerals Corporation, of Spruce Pine, N. C., shipped 583 short tons of topaz valued at $8,807 from the Brewer mine near Kershaw, S. C., in 1942; it was used entirely in refractories. Experiments are still being made by the Bureau of Mines regarding the substitution of properly calcined topaz or a product composed of domestic kyanite and topaz for Indian kyanite in refractories.

VERMICULITE

Sales of crude and exfoliated vermiculite, which originated in seven States, totaled 57,848 short tons valued at $319,931 in 1942. Production was more than twice that in 1941, when 23,438 tons valued at $125,444 were sold. Although the Universal Zonolite Insulation Co. (2601 West One Hundred and Seventh Street, Chicago, Ill.), operating properties at Libby, Mont., remained the predominant producer and processor, the number of smaller producers increased during 1942.

The increased production of this material is directly associated with wartime industries. Under normal trade conditions the principal use for expanded vermiculite has been in home insulation, a minor portion being employed in acoustical installation, lightweight plaster, cements, and coatings. However, during the war major uses of expanded vermiculite have been as an aggregate in lightweight and insulating concretes—principally in poured concrete for structural roof deck—

Digitized by Google

and in insulating roof and floor fills in temporary and permanent buildings. Vermiculite is also employed in deck coverings and firewalls of tankers that may be exposed to bombing attacks and by the petroleum industry for lining cracking units in refineries where vermiculite blocks or bricks serve both as refractories and insulators.

Virtually all vermiculite that enters the domestic market is cleaned and screened at the mine; some is exfoliated by the producers, or it may be sold to a processor for exfoliation. Screened vermiculite was sold to processors at $8 to $12 a short ton f. o. b. mine. The exfoliated material was quoted at 70 cents to $1.25 a bag—each bag containing 4 cubic feet weighing 25 pounds—or $56 to $100 a short ton f. o. b. works.

INTRODUCTION

The war year 1942 witnessed the operation of the mining industry of the United States with somewhat fewer men employed but with a large increase in number of man-hours of work performed. Copper, iron, lead, zinc, and other metals were in great demand by the Army and Navy; they were needed also for the manufacture of tools and other working equipment by civilian industrial plants engaged in producing airplanes, guns, tanks, and ships for the armed forces. Thus, the metal-mining industry was the original source of supply of raw materials of war. Back of the industries whose raw materials were of metal stood the coal-mining industry, without whose product the metal-using industries could not operate and the transportation systems of the Nation could not function. Faced with such conditions in 1942, the metal-mining industry and the coal-mining industry measured up to their wartime responsibilities. The difficult situation was met, so far as the mining and allied industries are concerned, by extension of the period of operation over a larger number of days during the year rather than by an attempt to increase the number of employees in the face of ever-increasing calls for men by the armed forces.

Reports thus far received (many companies not having yet reported) indicate that the mines, quarries, coke ovens, ore-dressing plants, and smelters in the United States employed approximately 812,600 men in 1942, or about 23,000 less than in 1941. However, operations during 1942, expressed in man-days of labor performed, reached nearly 211 million, a gain of 15 million man-days over the previous year. Expressed in another way, the volume of work performed was about 1.6 billion man-hours, compared with approximately 1.4 billion during 1941.

Digitized by Google

Accidents to the employees caused 1,878 deaths and 97,232 nonfatal lost-time injuries, such an injury meaning one that disables an employee longer than the remainder of the day on which he is hurt.

Based upon reports received by the Bureau, the mineral industries may be grouped into 22 classes, as shown in the accompanying table. Of these classes, 14 were operated with fewer employees than in 1941 and 8 with more. As the number of employees, however, does not necessarily indicate the extent of operations, the number of man-hours of work by the employees must be considered; on this basis, 15 classes showed gains and 7 showed losses. Of special note among the branches of the mineral industry that increased the number of man-hours of work during 1942 were mines and quarries or other plants that produced coal, iron, copper, lead and zinc, cement, limestone, coke, and such metals as mercury, manganese, and tungsten (included under "Miscellaneous" metals in the table). Gold mining experienced a loss in both number of employees and of man-hours worked, owing to the order of the War Production Board, which stopped or greatly reduced operations at mines whose principal output was gold-bearing ores.

Number of men employed [1] in the mineral industries of the United States, 1940–42

	1940	1941	1942 [2]
Coal mines:			
Bituminous	440,847	457,737	449,000
Pennsylvania anthracite	92,420	88,948	83,500
	533,267	546,685	532,500
Metal mines:			
Iron	23,250	25,870	28,100
Lead-zinc (Mississippi Valley)	7,644	8,634	8,800
Copper	19,498	21,576	22,600
Gold and silver lode mines (including lead, zinc, and copper, except as listed above)	39,128	38,235	29,900
Gold placer mines	15,701	13,368	12,700
Miscellaneous (tungsten, manganese, etc.)	5,119	6,614	7,000
	110,340	114,297	109,100
Nonmetallic-mineral mines	9,780	11,088	10,900
Quarries:			
Cement	26,695	28,859	30,200
Marble	3,240	2,693	2,400
Slate	2,800	2,845	2,400
Traprock	2,951	3,029	2,900
Granite	7,162	7,830	6,500
Sandstone	3,078	3,180	3,100
Limestone	23,251	26,395	25,900
Lime	10,332	11,292	10,500
	79,509	86,123	83,900
Coke ovens:			
Byproduct	17,469	18,633	19,500
Beehive	2,493	4,008	4,300
	19,962	22,641	23,800
Metallurgical plants:			
Mills	13,990	14,807	14,900
Smelters	20,120	22,003	20,700
Auxiliary works	14,958	17,539	16,800
	49,068	54,349	52,400
Grand total	801,926	835,183	812,600

An 11-year (1932 to 1942) review of accidents and employment in the 22 classes of the mineral industries of the United States is presented in the following table. Trend lines based upon the figures in the table are given in figure 1. As is evident from the table, the volume of employment, as measured by number of man-hours worked,

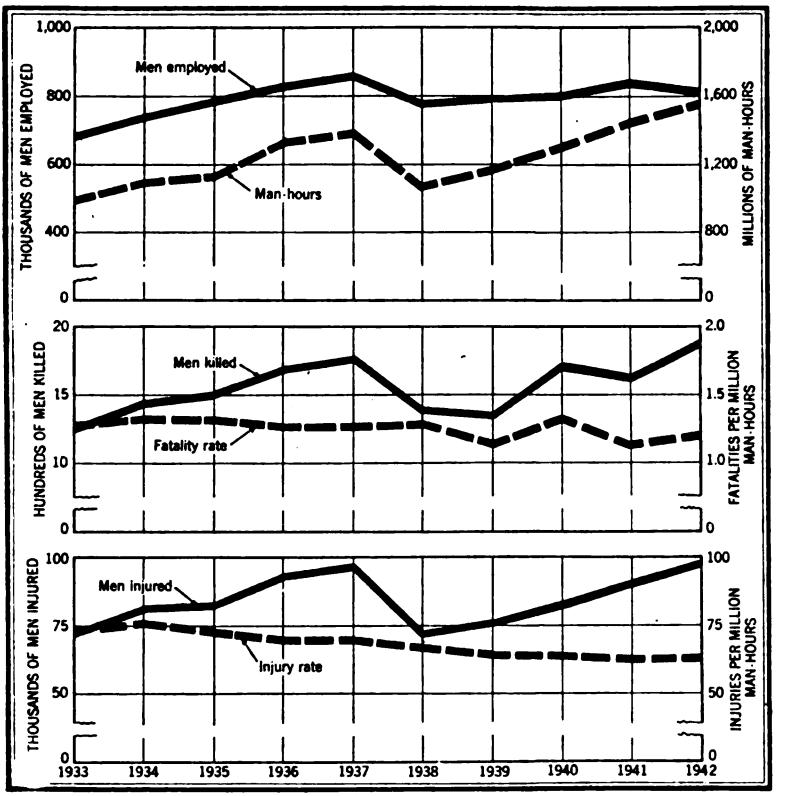

FIGURE 1.—Trend of employment and fatal and nonfatal accidents in the mineral industries of the United States, 1933–42.

reached its maximum in 1942. Maximum employment, as measured by the number of men working without regard to the number of days or hours available, was reached in 1937. The frequency of accidents in relation to the volume of employment in 1942, though not at the lowest point during the 11-year period, compared favorably with all other years except 1941.

1941	835,183	195,425,228	1,440,988,174	1,622	90,334	1.13	62.69
1942 [1]	812,600	210,778,000	1,550,206,000	1,878	97,232	1.20	62.72

[1] Subject to revision.

EMPLOYMENT AND ACCIDENTS

BITUMINOUS-COAL MINES

Employment.—More than 775 million man-hours of labor and a working force of about 449,000 men were required to operate the bituminous-coal mines of the United States during 1942. Production of coal reached 579 million short tons, or 12 percent more than in 1941; it exceeded the production of each year in the history of coal mining in the United States with the possible exception of 1918, the previous record year. About 2 percent fewer men worked in 1942 than in 1941, but the number of man-hours worked increased 12 percent. The large increase in production was the direct result of the heavy demand for coal for the industries of a nation at war, as bituminous coal is predominantly an industrial fuel and is the chief source of power on which other industries depend. The greater demand for coal was met with a smaller working force than in 1941 owing to the transfer of many coal-mine workers to the armed forces and, perhaps to a less extent, to the attraction of some employees to nonmining industries.

Accidents.—Accidents at the mines during 1942, according to present reports, killed 1,254 employees. This number, if confirmed by final reports, will indicate an increase of 182 over the number of miners killed in 1941. Nonfatal injuries increased by more than 7,400 and reached a total estimated at 54,125. The accident rate per million man-hours of employment during 1942 now stands at 1.62 for fatalities (slightly above 1941) and at 69.84 for nonfatal injuries, the latter rate being comparable with the previous year's rate of 67.49.

The year was marked by 6 major disasters in which 127 men were killed, as compared with 8 such disasters in 1941 when 73 men lost their lives. The six major disasters of 1942 were chargeable to four States—one each to Arkansas, Colorado, and Kentucky and three to West Virginia—and all were explosions.

Detailed information as to the causes of the more than 55,000 injuries and deaths in 1942 are not yet available and will not be known for several months, when reports from all mines in the United States shall have been received. However, a review of accident records over a period of years affords a typical picture of the cause-distribution of fatal and nonfatal injuries at bituminous-coal mines. For example,

Digitized by Google

during the 5-year period 1936 to 1940 accidents caused 5,247 deaths and 222,693 nonfatal lost-time injuries among the employees, a total of 227,940 personal injuries. Following are the percentages of the total number of accidents due to each main cause.

	Percent
Underground accidents:	
Falls of roof or face	27.8
Mine cars and locomotives	22.1
Handling materials	13.5
Hand tools	7.6
Machinery (cutters, loaders, etc.)	7.3
Falls of persons	3.6
Explosions of gas or coal dust	.6
Explosives	.7
Electricity	1.5
Miscellaneous	6.3
Shaft accidents	.2
Open-pit-mine accidents	2.6
Surface accidents	6.2
	100.0

A similar distribution of fatal accidents alone, which comprise only 2 or 3 percent of the large number of accidents, would show a different percentage distribution. The main causes of fatal accidents, in order of their numerical importance, are falls of roof or face, haulage accidents, gas and dust explosions, electricity, and machinery, these five classes covering about 88 percent of the total number of fatal accidents during any representative period in recent years.

ANTHRACITE MINES

Employment.—The output from mines of eastern Pennsylvania constitutes the product known as "anthracite" or "hard coal." Although a few other localities of the United States also produce hard coal, anthracite is usually identified with the coal-mining industry of eastern Pennsylvania. During 1942 the mines of this region produced and prepared for market approximately 58 million short tons of coal. This does not include several million tons from illegitimate or so-called bootleg mines, as reports of accidents or employment from such mines are not available. The regular or legitimate anthracite industry employed 83,500 men in 1942, according to reports available at present. These men worked approximately 144 million hours in and about the mines, breakers, preparation plants, washeries, and strip pits. Seven hours was the standard shift. Preliminary returns indicate that the collieries were operated about 246 days during the year, or 39 days more than in 1941.

Accidents.—Fatal accidents occurred to 228 men, an increase of 34 over the number reported for 1941. The number of nonfatal injuries increased also, the estimate for 1942 being 17,500, compared with 16,828 reported for the previous year. In relation to the increased man-hours of work, the record for 1942 was favorable, as the injury rate was 121.53, a decrease from 129.34 for 1941. The fatality rate for 1942 stands at 1.58, compared with 1.49 for 1941.

No major disasters have occurred in the anthracite mines of Pennsylvania since June 2, 1938, when an explosion of gas in a mine in Luzerne County caused the loss of 10 lives. This disaster-free record represents a period of 1,673 days to December 31, 1942.

Digitized by Google

IRON-ORE MINES

Employment.—Men employed and man-hours worked increased sharply in 1942. Incomplete returns indicate a total of 28,100 employees, a gain of nearly 9 percent over the year 1941. The total man-hours worked during the year was nearly 65 million, an increase of approximately 18 percent over 1941 when 54.9 million man-hours of work was performed.

Accidents.—Notwithstanding an increase in men employed and man-hours worked, continued progress was made in accident prevention. The accident-frequency rate was 22.69 per million man-hours in 1942, which compares favorably with the rate of 23.07 for 1941. The estimated number of injuries during 1942 is 1,466, including 51 fatalities.

COPPER MINES

Employment.—The demand for copper, due to the war, caused an increase in employment beyond that recorded in 1941, which was already substantially above the volume of employment in 1940. The number of mine workers reached approximately 22,600, an increase of 5 percent over 1941 and of 16 percent over 1940. Similarly, the number of man-hours of labor worked at the mines rose to about 58.8 million in 1942, from 55.1 million in 1941 and 48.7 million in 1940.

Accidents.—With increased employment and, hence, greater exposure to mining hazards, accidents in 1942 might also be expected to increase in number. However, present reports indicate no increase in the number for that year and an actual reduction in the accident rate per million man-hours worked. Both the fatality rate and the injury rate appear to have declined in 1942. Present information indicates a fatality rate of 0.83 and an injury rate of 49.99, compared with 1.14 and 53.71, respectively, in 1941.

LEAD AND ZINC MINES (MISSISSIPPI VALLEY STATES)

Classification.—This group covers mines producing lead and zinc in the Mississippi Valley States, chiefly Oklahoma, Missouri, and Kansas, and those producing fluorspar in Kentucky and Illinois, where somewhat comparable conditions prevail.

Employment.—The number of men working increased slightly in 1942, and the number of man-hours showed a decided gain. The number of employees was approximately 8,800, a gain of 2 percent. The aggregate man-hours worked increased about 13 percent, as preliminary reports for the year indicated 19.2 million man-hours worked compared with 16.9 million in 1941.

Accidents.—Tentative figures now available reveal that accidents increased in 1942 and resulted in a higher accident-frequency rate than in 1941. The accident rate increased from 59.35 per million man-hours in 1941 to approximately 65.81 in 1942. The safety record, therefore, was less favorable than in 1941. Accidents during 1942 caused 17 deaths and 1,247 injuries.

GOLD AND SILVER MINES (LODE AND PLACER)

Classification.—This group includes mines operated chiefly for the gold or silver content of their ores; it also includes mines outside the Mississippi Valley region whose ores were valuable mainly for the lead or zinc they contained, as well as mines that produced some copper

Digitized by Google

but whose ores were chiefly valuable for metals other than copper. Both placer mines and lode mines are included in the group.

Employment.—Employment diminished in volume in 1942, particularly during the latter part of the year, following the order of the War Production Board requiring the closing of many mines engaged chiefly in the production of gold. From a total of 51,603 employees in 1941, reports thus far received (for 1942) indicate about 42,600 men employed. Man-hours of work dropped from 90 million in 1941 to approximately 69 million in 1942.

Accidents.—According to present reports, accidents caused 85 deaths and 6,464 nonfatal injuries during 1942, representing a fatality rate of 1.24 and an injury rate of 94.33 per million man-hours worked, as compared with a fatality rate of 0.81 and an injury rate of 92.00 in 1941. Eight deaths were caused by a single disaster at a mine in Colorado.

MISCELLANEOUS METAL MINES

Classification.—This group includes all mines engaged in production of metallic ores exclusive of gold, silver, copper, lead, zinc, and iron. It therefore includes mines that produced such critical and strategic metallic ores (ores declared essential to the national defense) as bauxite, chromite, manganese, mercury, molybdenum, and tungsten, as well as various other minerals.

Employment.—Preliminary figures now available reveal that the production demands of a war economy have been partly responsible for raising employment in 1942 to approximately 7,000 men, or 6 percent over 1941. Man-hours of employment rose to over 15.1 million in 1942, compared with 13.8 million in 1941, or approximately 10 percent.

Accidents.—As estimated for 1942, the safety record was more favorable than that of 1941. The accident-frequency rate per million man-hours of employment was 81.30, compared with 85.03 for 1941. Present reports indicate that 17 men were killed and 1,213 injured by accidents in 1942.

NONMETALLIC-MINERAL MINES

Classification.—Included in this group are mines that yield any kind of nonmetallic mineral except coal, stone, sand, gravel, and clay. Hence, it includes all those that produce barite, feldspar, gypsum, sulfur, rock salt, mica, phosphate rock, and many other minerals.

Employment.—Employment in 1941 numbered 11,088 men, and in 1942, according to preliminary figures, the group as a whole employed approximately 10,900 men. The man-hours of employment, however, rose to 24.1 million, compared with 23.2 in 1941, or about 4 percent.

Accidents.—From reports now available for 1942, the accident-frequency rate was about 50.55 per million man-hours, which represents progress when compared with the 1941 rate of 51.62. Accidents during 1942 resulted in 19 deaths and 1,196 injuries among the workers.

CEMENT MILLS AND QUARRIES

Employment.—Approximately 30,200 men were employed in the cement industry (quarrying and manufacturing) during 1942, an increase of 5 percent over 1941. These men worked about 72 million man-hours, which was 11 percent more than in 1941.

556250—43——98

Digitized by Google

Accidents.—Increased employment in 1942 was accompanied by an increase in the number of fatal and nonfatal accidents. It is estimated that 46 men lost their lives during the year, including 28 who were killed in a single disaster caused by an explosion of dynamite; nonfatal injuries are estimated at 797. The fatality rate was 0.64 and the nonfatal-injury rate 11.10, compared with final rates of 0.22 and 10.93, respectively, in 1941.

MARBLE QUARRIES

Employment.—Employment at marble quarries and related plants in the United States continued to decrease in 1942. Employment is estimated at 2,400 men and 4.9 million man-hours, a decline from 2,693 men and 5.2 million man-hours for 1941. The proportionate decrease in number of man-hours of employment during 1942 was not as great as that in number of employees, hence an increase in number of days of employment per man.

Accidents.—Two men were killed by accidents, whereas no deaths were reported in 1941. The fatality rate for 1942 is estimated at 0.41 per million man-hours of exposure. Nonfatal injuries, estimated at 212, give a rate of 42.95, compared with a final rate of 46.33 for 1941.

SLATE QUARRIES

Employment.—Preliminary estimates indicate a decrease of approximately 16 percent in number of men employed in 1942. Employment expressed in man-hours was 4.8 million for the 2,400 men employed.

Accidents.—Two men were killed and 439 injured by accidents. The number of injuries was much larger than for 1941, when only 323 occurred. Based on these estimates, the fatality rate for 1942 was 0.42 and the nonfatal-injury rate was 91.14 per million man-hours, compared with 0.18 and 57.21, respectively, based on final figures for 1941.

TRAPROCK QUARRIES

Employment.—Preliminary reports indicate about 2,900 employees and 5.3 million man-hours worked in 1942. Employment in 1941 covered 3,029 men and slightly less than 5.3 million man-hours.

Accidents.—Accidents resulted in 5 fatalities and 256 nonfatal injuries, according to incomplete reports. These figures represent a fatality rate of 0.94 and an injury rate of 48.07 per million man-hours of employment and indicate a relatively large reduction in accident frequency.

GRANITE QUARRIES

Employment.—The estimated number of employees was 6,500, a decrease of 17 percent from the 1941 total. These men worked 1.5 million man-shifts or 12.7 million man-hours during the year. The decline in employment was due chiefly to the shut-down or curtailment of operations at dimension-stone plants and quarries.

Accidents.—Estimates indicate that 15 men were killed by accidents. This record compares unfavorably with that of 1941, which showed only 8 fatalities. Nonfatal injuries declined along with the decrease in employment, the number of such injuries having been 610, according to available data. Accidents in 1942 gave a fatality rate of 1.18 and a nonfatal-injury rate of 47.84 per million man-hours of employment; the rates for 1941 were 0.55 and 49.40, respectively.

Digitized by Google

SANDSTONE QUARRIES

Employment.—Employment changed very little in 1942 from 1941; estimates place the number of workers at 3,100, with a total of 5.7 million man-hours worked. As the number of man-hours decreased 3 percent, compared with the 1941 total, and the number of men employed was virtually unchanged, the working time per man declined in 1942.

Accidents.—Accidents in and about quarries and related plants resulted in death to 2 men and in lost-time injuries to an additional 336 men. Neither the fatality nor injury rate changed materially from 1941, when the record showed 0.34 and 59.76, respectively.

LIMESTONE QUARRIES

Employment.—Incomplete reports indicate that the number of men employed was about 25,900, a decline of 2 percent from 1941. However, the number of man-hours of employment increased 4 percent. Final returns for 1942 are expected to show a total of 48.7 million man-hours of work performed during the year.

Accidents.—Thirty men were killed and 2,540 men injured in accidents during the year. This is a decrease in nonfatal accidents from 1941, when 2,622 men were injured; however, the number of fatalities remained the same as in 1941. Thus, the fatality rate for 1942 was 0.62 compared with 0.64 for 1941, and the nonfatal-injury rate was 52.16 compared with 55.96.

LIMEKILNS AND ASSOCIATED QUARRIES

Employment.—The number of men employed, estimated at 10,500, was 7 percent less than the number employed in 1941. Despite this decrease, the number of man-hours of employment was 25.2 million, virtually the same as in 1941. Thus, the average employee had a longer work year—304 days or 2,400 hours; comparable figures for 1941 are 296 and 2,241, respectively.

Accidents.—Fortunately, the number of both fatal and nonfatal accidents declined substantially in 1942. Estimates indicate that 10 men were killed and 1,460 injured, compared with 17 and 1,551, respectively, in 1941. The 1942 fatality rate was 0.40 and the nonfatal-injury rate was 57.94, compared with a fatality rate of 0.67 and a nonfatal-injury rate of 61.30 in 1941.

BYPRODUCT COKE OVENS

Employment.—Final figures on employment during 1942 show 19,551 men employed, or 5 percent more than in 1941. They worked 56,771,172 man-hours, or 2,904 hours per man, during the year; man-hours of employment also increased 5 percent over 1941.

Accidents.—Accidents occurring among the employees killed 9 men and injured 545 during 1942. These accidents represent a fatality rate of 0.16 and a nonfatal-injury rate of 9.60 per million man-hours of employment, compared with 0.22 and 8.07, respectively, in 1941.

BEEHIVE COKE OVENS

Employment.—Present estimates indicate that employment in 1942 reached a new high level for recent years. Final returns are expected

Digitized by Google

to show that 4,300 men were employed for a total of 8.5 million man-hours.

Accidents.—Three men were killed and 375 men met with lost-time injuries from accidents during the year. These accidents indicate a fatality rate of 0.35 and a nonfatal-injury rate of 44.04 per million man-hours of employment. If these rates are unchanged by final returns they will be lower than the fatality rate of 0.43 and nonfatal-injury rate of 52.71 for the beehive-coke industry in 1941.

ORE-DRESSING PLANTS

Employment.—Gains in the number of workers and the man-hours worked in 1942, compared with 1941, were reported by ore-dressing and beneficiating plants. Men employed numbered about 14,900 and approximately 36 million man-hours of work was performed.

Accidents.—Incomplete data indicate an accident-frequency rate of 27.09 per million man-hours in 1942. As this rate is lower than the rate of 28.42 in 1941, the safety record for 1942 appears slightly more favorable than that of the previous year.

SMELTERS

Employment.—Included in the term "smelters," as used herein, are operations employed in the smelting and refining of all metallic ores other than iron ore. The smelting of iron ore and manufacture of steel are not included in the accident and employment statistics collected by the Bureau of Mines, as such statistics are collected and tabulated by the Department of Labor. Reports for the smelting industry indicate that 20,700 men were employed in 1942. This represents a loss of 6 percent in number of employees from 1941 but a gain of 3 percent over 1940. The man-hours of employment increased 3 percent, however, being 56 million in 1942.

Accidents.—The intense production effort occasioned by war demands resulted in a setback to accident prevention for the third successive year. The accident-frequency rate rose in 1942 to 30.49, from 27.05 in 1941, 19.70 in 1940, and 16.35 in 1939.

AUXILIARY WORKS AT ORE-DRESSING PLANTS AND SMELTERS

Employment.—All operations at mills and smelters not directly connected with milling and smelting processes are included in the term "auxiliary works." About 16,800 men were employed in such works in 1942, a decrease of 4 percent from 1941. Despite this loss in number of employees, man-hours worked increased about 4 percent, reaching 44.8 million.

Accidents.—The accident-frequency rate for 1942 increased slightly, being 20.65 per million man-hours compared with 20.06 in 1941.

SUMMARY, 1932–42

Absenteeism has become widely recognized as a factor in the slowing down of production of war materials. Also widely recognized are certain contributions to absenteeism. Among these are insufficiency of supplies when needed, inadequacy of transportation facilities, strikes, lock-outs, sickness, and accidents. Perhaps accidents are least widely recognized as contributors; and perhaps even less appreciated, not only by the public but by many production experts, is

Digitized by Google

that saboteur of war energy, the preventable accident. Although all will agree that some risk of personal injury is inherent, or seemingly inherent, in industry, there can be no justification or excuse, even in wartime, for most of the accidents that occur.

On several recent occasions the attention of the public and of industry has been called by the President of the United States to the importance of conserving manpower through the prevention of accidents in factories, on farms, in mines, and on the highways and railways of the country. It has become conventional to recite some of the leading causes of these accidents. The public has to some extent become familiar with such recitals. To safety engineers they are an old story. But perhaps it may justly be said that the chief cause of all accidents in the mineral and other industries is the small amount or complete absence of thought given to the importance of accident prevention by those who do not have safety thrust upon their attention every day. To such persons, in many instances, the safety engineer must look for the approval and support of his safety programs. Until the safety engineer occupies a position in his organization equal to and not under that of the production engineer, industrial workers will continue to be killed and injured by preventable accidents, and the rehabilitation of needlessly injured persons will remain a major and serious problem demanding the attention of governmental and other agencies.

In 1942, a year in which the Nation could ill afford a loss of manpower from any cause, between 3 and 4 million man-days were lost because of accidents in the mineral industries alone. This loss was from injuries classed as "temporary", so called because in each instance the injured employee was ultimately able to return to work without having lost a leg, foot, arm, or other part of his body. A loss of manpower nearly as great arose from injuries classed as "permanent injuries", as the accident caused the loss of some part of the body or of its use. Such cases are considered equivalent to the loss of 6,000 work days when they permanently and totally incapacitate an employee.

Applying this thought to the coal-mining industry alone it may be observed that as the over-all average of production of coal in the United States is about 4.9 tons per man per day, the loss of time from "temporary" injuries alone represented a production loss of 15 or 20 million tons of coal during 1942. An additional and even larger loss, not confined to 1942, must be charged for deaths and permanent-total and permanent-partial disabilities caused by accidents. Such losses are continuing, owing to the permanent impairment of the miner's ability to work and, in the case of deaths or permanent-total disability, owing to the absolute cessation of the miner's ability to produce coal.

In the face of such losses, which are but a repetition of a record that has continued for many years, there can be little doubt that one of the most important problems facing the Nation is the prevention of industrial accidents. It is to be hoped that when the war is won, the safeguarding of the lives and limbs of industrial workers will be advanced to the front ranks among subjects universally recognized as meriting first consideration of production engineers and executives of industry.
